The organization of the Central Office only roughly corresponds to the extensive and convoluted governing structure. The Central Office table of organization as of December 1970 appears in this article (p. 166) but should be taken with a grain of salt. It changes as problems and personnel come and go and sometimes just for the hell of it.

The lack of exact correspondence is explicable if one accepts the fact that the APA is about 80% a business (only in 1971). This means that about half of its revenues (and half of its expenses) are for direct services and products. The Association receives the money and continues to deliver, for example, 12 issues of a journal on accreditation with a copy of the Graduate Manual, handles a PANAM search a convention on advertisement in the *Professional Review* or arrangements for a Head Start consultant to a regional center for the U.S. Department of Health, Education and Welfare (HEW). An enormous amount of services or products is delivered for free to the recipient. For example, at no cost to the recipient, a number of associations can obtain them in 1973. In APA services in promotion of an association's members (or biologist and ecology listed associations of various sorts are given some assistance. Un- business operations have no direct parallel in the governing structure but are run by the Executive Officer and staff under the supervision of the Board of Directors.

This business-like character of the Association markedly limits the amount of discretionary resources available for Association-wide nonbusiness promoting activities. As in the nature of business activities, and APA is an exception, they are the

¹Report made to the Council of Representatives of the American Psychological Association, Washington, D.C., January 10, 1974.

AMERICAN PSYCHOLOGICAL ASSOCIATION
CENTRAL OFFICE ORGANIZATION

menhently dependent on events beyond their control. No vote of APA could stop the rise in postal rates March 1; no vote of APA will increase the amount and quality of paper available to our printers; no vote of APA can halt the inflation in our economy.

Since there is a positive and significant relationship between Association expenditures and a number of Central Office staff members, clearly a great deal of our work is devoted to business activities. For the remainder of staff time and effort, the next largest portion is in logistic support of boards and committees of the policy- and decision-making arm of the Association as well as operational committees. It is spent on such things as preparation for meetings, including accumulating agenda items from various sources, working up an agenda with background data, making physical arrangements for the meeting, participating in the discussion and taking notes, perhaps writing the minutes, acting as a resource person, and following up on actions of the committee to make sure that the several stages of the decision process are covered and the decision itself is implemented when approved. As a lower estimate, 150 meetings of APA boards and committees took place last year involving a minimum of 300 individual staff member days merely sitting in meetings for which the individual had direct responsibility. For the primary staff member, an additional several days are involved in preparation for the meeting and several more are spent in following up on its details.

The staff member days in meetings are increased substantially by the fact that most involve more than one staff member. A Board of Directors or a Council meeting may require the presence or availability of over 75% of the professional staff. In 1973 it looks as if the record will be, for one staff member, over 60 working days of meetings or 12 working weeks in board and committee meetings. This might help explain why the staff winces each time the Association proposes to establish yet another such group. To these Association meetings must be added the regular and ad hoc liaison meetings with outside groups: the Scientific Manpower Commission, the National Advisory Mental Health Council, the American Federation of Abstractors, the National Research Council, and the other 30-odd organizations with which liaison is maintained.

What does the Central Office staff do with the balance of its time? To a large extent it answers mail or otherwise serves in an information-dis-

persing role. Well over one million pieces of mail arrive at 1200 Seventeenth Street each year (28 tons of it in 1973), only a small portion of which are dues payments or even complaints. The vast majority are questions from teachers, from students, from the general public, from legislators and government officials, and from writers. You name it, we get it and we answer it. Of course, no one office deals with this correspondence. Central Office staff members at senior levels are selected for competence and knowledgeability about certain areas and can deal with most of the questions that arise. Most staff members soon learn considerably more than they knew when they came on board or perhaps wish to know. In addition, the Central Office maintains formal clearinghouses in precollege psychology, psychology's manpower, and research funding sources, as well as an administrative section for general correspondence.

With that general overview of Central Office functioning, let me turn to 1973. From the program staff's point of view, it was a miserable year largely because of the politicization of the Association, the instigation on false pretenses of a special meeting of Council, and a barrage of general and personal invective directed against the Board of Directors, the Executive Officer, and the Association. A certain amount of this nonsense is accepted as normal APA operating procedure, particularly when it comes from the Association's own boards and committees, but the directed and virulent attack from representatives of an outside organization during 1973 was remarkable. The impact was twofold: First, the always precarious morale of the Central Office staff was further undermined, and, second and much more important, an enormous amount of staff time was wasted in assembling materials and data and preparing evaluations and reports. I say wasted because the effort seemed to have no effect in reducing the generation of ill-advised or downright foolish proposals. The staff time spent on such things necessarily had to be diverted from other, more worthwhile activities.

Fortunately, such antics have had little effect on the 80% of Association and Central Office business activities to which I referred earlier. If they had, the Association would have really been in bad shape. The impact has been felt most among the program staff, an impact that was heightened by the work demands of a 35% increase in board and committee meetings in 1973 over 1972.

With that foreword, let me proceed to the several

Offices and their 1973 activities. The Central Office is organized into five major offices: Communications, Programs and Planning, Business Affairs, External Affairs, and the Executive Office. These are described and discussed seriatim.

Office of Communications

This office, the largest of the Central Office units (67 staff members), is divided into three major departments: Publications, Psychological Abstracts Information Services (PAIS), and Publications Development. The Director is Harold Van Cott.

PUBLICATIONS

This department, under the direction of Anita DeVivo, Executive Editor, is responsible for the production of APA's 14 primary journals. In 1973 the journals contained 15,000 text pages, each of which had been carefully redacted for accuracy and format by one of the Association's 17 technical editors. Text pages were up by 1,000 over 1972 and total subscriptions to the journals exceeded 150,000. Such statistics are probably of little interest to people other than editors or publishers; of more importance to APA members is the preparation of a major revision of the *Publication Manual* due out in 1974 and the preparation for the subsectioning of the *Journal of Experimental Psychology*. The last was described in some detail by Arthur Melton in the January 1974 issues of the *APA Monitor* (p. 3) and the *American Psychologist* (pp. 65-66).

PSYCHOLOGICAL ABSTRACTS INFORMATION SERVICES

The activities of this department, under the direction of Robert Kinkade, Executive Editor, are the publication of *Psychological Abstracts (PA)* and the provision of products and services derived from the *PA* tapes. In 1973 we provided 24,407 abstracts on 5,000 pages to over 8,000 subscribers. Starting in 1973 the *PA* indexing system was increased from 800 terms to 3,000, thus making location of documents in *PA* much easier. As a spin-off of the new *PA* classification and indexing systems, a *Thesaurus of Psychological Terms*, a valuable reference tool for all psychologists, will be produced. This should be available to the public in mid-1974. A new PAIS product was issued in 1973: three-year cumulative author and subject indexes to *PA*.

These were previously produced by G. K. Hall under a royalty arrangement, but will now be published directly by APA at three-year intervals at a substantially increased net profit.

The year 1973 also saw continuation of the transfer to APA of formerly contracted services for the publication of *PA* magnetic tapes. By 1974 all *PA* composition will be done in-house with our own computer at considerable savings.

Three interrelated PAIS tape services—PATELL, PADAT, and PASAR—provide access to the *PA* file from 1967 to the present from remote terminals (PADAT), by mailed search requests processed at APA (PASAR), or by search of the *PA* tape file under lease of that file (PATELL). By the end of 1973, 32 organizations had access to the *PA* file through remote terminals; PASAR requests averaged 20 per week over the year, increasing each month during the year; and leases of *PA* tapes (PATELL) had been negotiated with two foreign countries and five United States universities and research organizations.

Despite the expansion of PAIS during the year, in 1973 for the first time *PA* showed a surplus after many years of deficit grant support. The new products and services derived from the *PA* computer tape file also showed a modest surplus at the year's end. The Psychological Abstracts Information Services are now among the most advanced and useful abstracting and indexing systems in science and technology.

PUBLICATIONS DEVELOPMENT

This department, with Elliot Siegel, Manager, has as its major activities the production of separates (books and pamphlets published by APA); the Journal Supplement Abstract Service; and the management of all royalties, permissions to reprint, and other republishing arrangements. Five separates, including the *Convention Program* and the *Proceedings*, were published in 1973 with the *Psychology of Adult Development and Aging* being—for APA—a best-seller.

The Journal Supplement Abstract Service (JSAS) is an experimental publication service featuring on-demand dissemination of separately bound copies of original psychology materials. The manuscripts are reviewed by a 10-member editorial panel, and abstracts of accepted articles are published in the quarterly *Catalog of Selected Documents in Psychology*. Started in 1972, JSAS had 1,400 subscribers and had received 4,200 document orders at

the end of October 1973, an increase of 100% over the previous year. Two APA divisions, 19 (Military) and 21 (Engineering), have adopted JSAS as their official publication source, and for 1975 Division 21 has approved a member assessment to cover the cost of subscriptions to the JSAS abstracts. Optional subscription to JSAS was listed for the first time on the 1974 member dues bill, and a thorough evaluation of its use and finances is planned in 1974. With the advent of machines that will reproduce copies of documents from microfiche at low cost (JSAS documents are now photocopied for users) expected at any time, JSAS may well become a prototype for publications systems of the future.

During 1973 all APA activities concerned with the secondary use, distribution, and sale of previously published APA journal articles were combined into a single program. This program encompasses the potential sale and distribution of single articles and collections of articles as reprints, the granting of copyright permission authorization for the one-time use of single articles, the permission authorization for the one-time use of single articles, and the negotiation of long-term contractual agreements that assign rights to republish materials (by run, volume, year, or article). One development in this area has been the renegotiation of contracts that allow organizations to sell microform and microfiche editions of APA journals and JSAS documents. Now, for the first time, anything that APA publishes in serial form can be obtained on film, with suppliers paying APA royalties ranging from 20% to 25% of revenues. Another development is a plan for an APA reprint service. Initially, this service would make available on demand reprints of articles appearing in the *American Psychologist*. If successful, reprints from other journals may be added. A properly designed reprint service would provide single copies for individual scholarly users and multiple copies for classroom and group use, thereby reducing the temptation to copy illegally.

The Central Office had faced the 1973 communications program with trepidation. Twelve years of research and development grant funding for a National Information System for Psychology (NISP) came to an end in 1972. Deficit grant support for *Psychological Abstracts* averaging \$100,000 a year for a decade also ended. New products and services, such as the Journal Supplement Abstract Service and the *Psychological Abstracts* computer-based services, were still too new

for their success to be predictable. Cuts in library budgets, paper shortages, and rising costs were expected to affect even such traditional products as the journals. Controversy over NISP and its Experimental Publication System still echoed in some ears. And while much had been done to plan and complete several elements of NISP, other important tasks awaited completion. Thus, we had financial, political, and technical reasons for worry. Similarly, the effect of the decision to eliminate the dues credit for journals was an unknown factor lurking on the 1974 horizon.

As the year ended, however, it found the program in reasonably good shape, and loss of revenue for 1974 from elimination of the journal credit only slightly exceeded projection. The years 1974 and following are undoubtedly going to have their problems, two of which are almost upon us. The first is the ongoing consideration being given by Congress to revision of the copyright laws and recent court decisions permitting almost unlimited free duplication of published scientific and technical articles. The communications program produces close to \$100,000 in royalties and reprint payments, an amount that may be in serious jeopardy.

As paper shortages continue and prices rise, and as printing costs mount, the exploration of alternatives to our present methods of journal production has become essential. To give you some idea of our dependence on this material, if you stacked all copies of the journals, the abstracts, the *APA Monitor*, and the separates we have produced one on top of the other, you would have a column over six miles high. As a first step in addressing this problem, cost comparison studies are being made by staff between hot and cold type methods of printing, and the journal staff has taken preparatory orientation training in photocomposition—a method widely used to publish encyclopedias, telephone books, and *Psychological Abstracts*.

Regardless of the techniques to be adopted in the future to combat rising production costs, paper shortages may ultimately force APA, as well as other publishers, to use nonpaper materials for information storage and dissemination. One benign solution would be to print less on paper and to use microform for extensive data tabulations, minor studies, and backup information.

Office of Business Affairs

The Office of Business Affairs, the second largest of the four offices, consists of six departments and a

total staff of 55. The Director of the Office is Boris E. Cherney. The several departments are discussed below.

MEMBERSHIP

This department is under the direction of Jane Hildreth, who has been with the Central Office since its inception in 1946; it has, in addition to Jane, three other staff members. The department processes all applications for membership in APA; applications for Students in Psychology, High School Teacher Affiliates, and Foreign Affiliates; changes in membership status; and requests for division membership. It also handles the thousands of pieces of correspondence each year from members and affiliates. In 1973, the department processed 3,164 applications for membership in APA, resulting in 2,907 individuals being elected for 1974, the largest number in APA history. For comparison, in 1972, 2,655 new members were elected. At the end of 1973 there were 35,000 members, 7,000 students, 750 foreign affiliates, and 550 high school teacher affiliates—in all, a grand total of about 43,000 persons.

CONVENTION

This department is headed by Candace Won, Assistant for Convention Management, and is a one-person department. She is responsible for the logistics aspects of the annual convention, coordinates the requirements of divisions for hours and meeting rooms, and works closely with the Convention Manager, Theodore Driscoll, and the staff of Driscoll and Associates. In addition, Candace Won processes advance registration, prepares the annual *Call for Papers*, and assists the APA divisions in developing the program. In 1973, the convention was held in Montreal, Quebec, Canada, and was attended by at least 19,000 persons, 12,500 of whom registered, with 6,500 persons accompanying the registrants. For contrast, the number of persons attending the 1970 (Miami Beach), 1971 (Washington, D.C.), and 1972 (Honolulu) conventions was about 13,000, 15,000, and 11,000, respectively. In each case, about two thirds of the attendees were registered. The 1974 convention is scheduled for New Orleans and is expected to attract about 15,000–17,000 persons.

PLACEMENT

This department is headed by James Beauter and has one additional staff member. Responsibilities

include publication of the monthly *Employment Bulletin* and the conduct of the placement service at the annual convention. Currently there are 3,800 subscriptions to the *Bulletin*, which, for the 12 issues in 1973, listed 884 positions open for recruitment and 224 availabilities of persons for employment. At the 1973 Montreal Convention, there were 164 employers present and another 141 employers who had listings in the *Annual Convention Placement Bulletin*. Together the employers were recruiting for 574 positions while 521 applicants were seeking positions. In addition to the APA placement service, the department supports regional associations by preparing the *Regional Placement Bulletin* used by those associations in the conduct of their local placement operations.

ADMINISTRATIVE SERVICES

This department is headed by William W. Carpenter, who is assisted by 16 other staff members. Their functions include support of the APA governance system, mainly the Council of Representatives and the Board of Directors, during preparation for, the course of, and the mopping up after meetings. It also handles hotel reservations for all board and committee members attending meetings in Washington, D.C., maintains a central repository for minutes of all APA board and committee meetings, and is responsible for the regular updating of the Rules of Council. The department also provides support for the Central Office staff by making purchases, maintaining an office supplies room, handling incoming and outgoing mail, running a print shop, and in general being responsible for all housekeeping functions including property management of the APA headquarters building for both APA itself and its tenants.

A few statistics: The number of impressions produced in the print shop in 1973 was 3,800,000 (adding another quarter of a mile of paper to the stack of paper) in contrast to 3,700,000 in 1972; the number of board and committee meetings serviced was 150 in 1973 versus 111 in 1972; the number of bags of mail received was 1,124 in 1973 versus 1,108 in 1972; and the number of bags of mail shipped out was 2,415 in 1973 versus 2,232 in 1972. We mailed 125,000 copies of nonperiodical publications in 1973 versus 114,000 in 1972; and, finally, our postage bill for correspondence and materials shipped out went up to \$60,000 in 1973 compared to \$52,000 in 1972.

Such statistics as I have just cited may seem

trivial and indeed they are—taken in isolation. The staff uses them as trend indicators of Association activity, particularly that of members of the governing structure. When the percentage increases in such measures and starts diverging excessively from the percentage of increase of revenues over expenses, we are in trouble. Unfortunately, this is what has been occurring during the past three years.

FINANCIAL SERVICES

This department is under the direction of the Controller, Charles L. McKay, assisted by seven other staff members. It maintains and develops the financial systems and records of the Association as needed to protect the assets of the organization and provides timely financial reports, budgets, forecasts, projections, and other financial statements and data required by the management. During 1973, the department cashed 100,000 checks and wrote 11,000. By contrast, in 1972 the department cashed 87,000 checks and prepared 10,000 disbursement checks. During 1974, there are plans to further computerize operations in a continuing effort to mechanize the accounting system.

PUBLICATIONS BUSINESS AND COMPUTER SERVICES

This department is headed by Forrest Mullins and consists of the two divisions described below.

The Publication Business Services Division consists of 10 employees and is primarily responsible for processing publication orders received from members and nonmembers. The department also promotes and handles all advertising carried in APA journals. Several of the more significant factors contributing to the department's 1973 workload were the receipt of approximately 5,800 letters of inquiry and other member correspondence during 1973 versus 5,000 received and answered in 1972; 2,710 advertising orders processed in 1973 as compared with 2,380 in 1972; and total invoices prepared in 1973 of 9,450 versus 8,900 in 1972.

The Computer Services Division, managed by William Rodgers with a staff of nine other people, underwent a transition during 1973 which has greatly improved and increased our internal computer capabilities. A Burroughs B-2500 System with four tape drives and a large capacity for disk storage and retrieval was installed to replace a less sophisticated card-processing computer. As mentioned earlier, we are now, therefore, performing

certain work for Psychological Abstracts and Manpower Resources formerly done by outside contractors. The result is a net savings to APA. Additional computer upgrading features will be installed in early 1974 which we expect will result in even greater economies. For information, this division keypunched and verified 604,000 cards in 1973 compared to 506,000 in 1972; produced 1,990,000 mailing labels for journal subscribers in 1973 versus 1,810,000 in 1972; and produced 3,533,000 labels for sale versus 3,182,000 in 1972. The last item produced \$80,000 in revenues in 1973 against \$65,000 in 1972.

Office of Programs and Planning

Within the Office of Programs and Planning are the five departments that represent the greatest proportion of the nonpublishing, nonsupport activity of the Association. Although I say nonpublication activity, the staff of Programs and Planning was responsible in varying degrees in 1973 for putting together the *Biographical Directory*; the *Consolidated Roster*; the *Graduate Study* booklet; the *Ethics of Human Research* booklet; several publications primarily for high school and two-year college teachers; at least five newsletters; and a sizable number of reports in the *APA Monitor*, the *American Psychologist*, and the Journal Supplement Abstracts Service. Work is currently proceeding on a revision of the *Career* booklet, a booklet on test standards, and several other information pieces. The Office consists of the five departments described below and has as its Director C. Alan Boneau, who is assisted by 32 additional staff members.

EDUCATIONAL AFFAIRS

The focal areas of activity in Educational Affairs are precollege psychology, the teaching of psychology in two-year colleges, graduate programs, professional training, continuing education, and accreditation of training programs. It is headed by J. R. Nazzaro with Ronald Kurz as Associate Administrative Officer.

In precollege psychology the staff has concentrated in 1973 on projects to provide materials for teachers, and two major outcomes of this effort can be reported to you at this time. The first is the publication of the *Psychology Teacher's Resource Book: First Course*, an updated and revised version of the previous publication, *Program on the Teaching of Psychology in the Secondary Schools*. A sec-

and activity concerned with materials for teachers involves the preparation and submission of a grant proposal to the National Science Foundation for the development of curricular materials. A good deal of staff time this year was spent in negotiation with NSF on the details of the project, the grant, \$150,000 for the first year, was received on January 18, 1974. In precollege psychology, the staff has also been concerned with standards for training in certification of behavioral science teachers and has been engaged in data-gathering efforts involving surveys of teachers and colleges. The Educational Affairs staff established a system of liaison with state psychological associations which to date has over 30 individuals coordinating precollege psychology activities at the state level. A newsletter had been initiated to exchange information among them.

In the area of the two-year colleges, the staff has surveyed nearly 4,000 two-year college psychology instructors in an attempt to determine needs of these individuals that could be met by the APA. Again it appears that the Association's role will be to coordinate state activities because the primary felt need of two-year college teachers was for locally sponsored workshops.

In the area of psychology in the graduate schools, the booklet *Graduate Study* has been published under a new format that provides considerably more standardized information to students about programs, program requirements, and program expectations. This information also proved highly useful to the participants at the Vail Conference. The department also conducted its annual enrollment, degree, and graduate employment surveys and is now handling the annual faculty salary survey formerly conducted by the National Council of Chairmen of Psychology Graduate Departments. The staff is currently working on standardization of application and recommendation forms as a possible step toward systematizing the application and selection procedure for graduate schools.

A significant portion of the department staff activities was the administrative arrangements for meetings and visits. Viewing the accreditation program in this fashion, 44 visits were arranged, 14 applications processed; 216 reports received, analyzed, and prepared for review by the Committee on Accreditation. The department also administers the Visiting Scientist Program, now APA funded, and arranged 73 visits to small colleges, including 13 visits by minority consultants to predominantly

minority institutions. For the Visiting Psychologist Program providing consultation to training agencies, the staff solicited applications from more than 5,000 agencies, received 116 completed applications, and arranged for visits to 39 of them. The Educational Affairs staff also carried out the administrative arrangements of the Vail Conference with its 140 participants and also participated in structuring the conference, in staffing the meeting, and in following up on the correspondence and the conference report activities after the conference itself.

SCIENTIFIC AFFAIRS

This department, with Miriam Keltz as Administrative Officer, has been, during 1973, concerned primarily with science policy, the ethics of research, population, psychological testing as applied to employment and educational selection, and research funding. In the area of science policy, the staff monitors developments within the federal government and reports these to the Association membership. The reports, in 1973, included anticipated changes in the peer review system for grants, the implications of New Federalism for psychology, and the reorganization of DHEW.

In the ethics of research, the Scientific Affairs Department has provided the administrative staff for the activities of the Committee on the Conduct of Psychological Research with Human Participants and has arranged the preparation and dissemination of the report of that committee. It will be available this year as an APA separate. The staff also has disseminated proposed regulations and legislation dealing with human experimentation to knowledgeable segments of the membership, collated their responses, and submitted to Congress and DHEW compendia on views of psychologists with regard to proposed restrictions of research with human subjects.

In psychological testing, the Department of Scientific Affairs' staff has suffered, along with the Committee on Psychological Tests, through the development of the revised manual *Standards for Educational and Psychological Tests*. It conducted three public hearings on the document to solicit opinions of the draft and collected and collated the disparate views for the Committee. Also in the general area of employee selection procedures, the staff of the department provided technical consultation to the Equal Employment Opportunity Coordinating Council in its drafting a document on employee selection and arranged and promoted a

public hearing for psychologists to comment on the draft.

With respect to research funds, the staff has maintained communication with several of the federal agencies, reporting anticipated policy changes, and arranged three staff seminars with the research grants staff of the National Institute of Mental Health, the National Science Foundation, and the Department of Defense. They also conducted a survey for the Board of Scientific Affairs of a small number of graduate departments to determine the effects on those departments of the reductions in research support. The results, however, were inconclusive. In addition, more than 400 foundations were surveyed to explore their actual or potential sources of support for psychological research and/or training. These activities in conjunction with similar activities of the Educational Affairs Office provide within Central Office a major clearinghouse function dealing with information about funding for psychological research and training.

PROFESSIONAL AFFAIRS

Professional Affairs has been headed since last April by Arthur Centor with Gottlieb Simon as Associate Administrative Officer. The major areas of concentration in 1973 have been state association affairs, health profession matters, legislative and governmental affairs, standards for service, and several special projects. For the state associations, the effort has been to provide information as a basis for activity in newly emerging and critical areas of psychology. Working with Public Affairs, the staff started early in 1973 to develop an awareness within state associations of the implications of the New Federalism and has maintained a continuous liaison through a Central Office newsletter aimed primarily at those associations. A series of information packets were prepared describing the New Federalism philosophy and ways in which state associations could mobilize themselves to find different sources of support for training research and service. In health affairs, Professional Affairs staff support for the Committee on Health Insurance included production of a new and enlarged edition of a health insurance information packet and participation in negotiation meetings with the insurance industry and Blue Cross Blue Shield. The department has also been involved in drafting guidelines for professional standard review committees and a national network of state-sponsored professional standard review committees. In addition,

they have been directly involved in helping to define and organize the National Registry of Health Service Providers in Psychology, coordinating the concerns of APA with those of the other interested participating groups.

A considerable amount of staff effort was taken up by APA's project to develop standards for service facilities. This NIMH-funded project has Arthur Centor as its principal investigator. He also serves in the same role for the Office of Child Development-supported project to provide psychologist consultants to each DHEW region on the delivery of mental health services in local Head Start programs.

One rather unusual project of Professional Affairs this past summer was an attempt to assess professional psychological activity in the public interest and the factors that promote such activity. In this project, college students interviewed professional psychologists in the Washington, D.C., area. A report and set of recommendations are currently being written.

SOCIAL AND ETHICAL RESPONSIBILITY

In the Department of Social and Ethical Responsibility, headed by Fred Strassburger, there are two sections. The first is concerned with the ethics program of the Association and involves voluminous correspondence and intricate procedural arrangements. Brenda Gurel, Ethics Officer, and the staff working with the ethics program have been helping the committee revise its rules and procedures. This job, completed this year with the bylaw changes sent to the members will greatly simplify and streamline the processing of ethics cases. Staff has also conducted ethics workshops and seminars with state groups and has served as consultant to several other associations for which a liaison in matters of ethical conduct is appropriate.

In the area of social responsibility itself, the first of staff activities have been in the area of women's rights, minority rights, and with a number of special concerns of the Board of Social and Ethical Responsibility for Psychology. The department completed a resurvey of department chairpersons of psychology and is currently tabulating the results and preparing a report on the status of women and minorities on psychology faculties. It also completed a file of women psychologists, by specialty, for use by the Committee on the Status of Women in Psychology in suggesting journal reviewers and nominations for boards and committees. An addi-

tional activity in the area is an informal clearing-house handling requests for information on qualified women job applicants and on equal employment opportunity problems and programs for women. The staff also organized a symposium of interest to women in psychology for the Montreal Convention.

The Social and Ethical Responsibility Department in cooperation with Educational Affairs developed and administered the program of consultants for minority affairs to colleges. It was a special part of the Visiting Scientist Program. The year 1973 also saw a continuation of the vendors project and the development of an APA affirmative action plan. Finally, there has been considerable participation by the Central Office staff in the activities of the Board of Social and Ethical Responsibility, particularly with respect to the concern about prisoners of war.

MANPOWER RESOURCES

The Manpower Resources Department, headed by Thomas Willette, has, as its name implies, responsibility for the design and development of the APA Manpower Data System. In 1937 the 46,000 questionnaire records received from the 1972 Survey were processed and converted into a computerized data file. Using this file, the Manpower Resources staff devised specifications and supervised the efforts of commercial firms in producing the 1973 *Biographical Directory* and the *Consolidated Roster for Psychology*, both of which were published during the past six months.

A major task for the staff has been the design and testing of software, for maintaining and updating the file, for editing records, for statistical tabulations, and for search and retrieval work. As a result of this, the data base is now a major source of information about psychologists and their activities. Several general tabulations of the data have been already made, and a number of analyses and studies have been planned and are now in various stages of completion. The questionnaire is now being redesigned for mailing in 1974 to produce a revised, updated, and corrected 1975 *Biographical Directory*.

Office of External Affairs

This office, the next to the smallest of the Central Office units (10 staff members), is divided into three departments: Public Information, International Relations, and Public Affairs. Departmental

distinctions tend to become blurred, however, because of the small size of the staff. The Director of the Office is Harley O. Preston.

PUBLIC INFORMATION

The director of this department is APA's Public Information Officer, James F. Warren, who also serves as the editor of the *APA Monitor*. The *APA Monitor* has continued to grow in size and circulation faster than predicted. In 1973 its paid circulation reached 43,700 subscribers, exclusive of a sizable free distribution to public officials, representatives of the various news media, and give-away copies. There were four 16-page issues, two 20-page issues, three 24-page issues, and one 32-page issue. The Convention issue consisted of 40 pages, with approximately 20 pages of paid advertisements. Innovations in 1973 included the publishing of pro-con articles on certain selected psychological controversies, extended and in-depth feature articles on governmental programs or proposals, and the use of separate supplements to disseminate drafts of major APA reports for member comments and criticisms.

The Public Information Department received and processed 162 entries for the 1973 National Media Awards Program of the American Psychological Foundation. It also conducted seminars for members of the working press at two regional meetings and at the Annual Convention in Montreal. The purpose of these seminars is not to generate "spot" news—this is done through the APA Press Room also conducted by this department—but to promote more accurate reporting of psychological information by science writers for the daily press, magazines, and television.

The department continued to send special press releases monthly to collegiate and weekly newspapers as well as issuing regular press releases on major happenings involving the APA and individual psychologists. It also continued its practice of hiring a journalism intern for the summer months. The 1973 intern was a student from the Kansas State University School of Journalism.

INTERNATIONAL RELATIONS

The Director of External Affairs also acts as the head of this department. Much of the activity during the first part of 1973 dealt with continuing activities from the 1972 International Congress of Psychology in Tokyo, and commendation was received from the National Science Foundation on

the APA's formal report of this important international meeting. Other activities have included the opening of contacts with psychologists and educators in the People's Republic of China, increasing interest and participation of American psychologists in the social science programs of UNESCO, recruitment of faculty members for universities in developing countries, and providing staff support to APA official representatives to the International Union of Psychological Sciences and to the U.S. National Commission for UNESCO.

The past year also began APA's organizational affiliation with the American Council of Learned Societies. It is too soon to report any results from this affiliation, but it should mean increased support for international activities for psychologists working in the history of psychology, philosophical psychology, and psychology in the arts.

PUBLIC AFFAIRS

This department is directed by Harry R. Seymour, who also serves as principal adviser to the Executive Officer and Central Office staff on APA's legislative activities.

During 1973 the department prepared (or had prepared) and distributed to the APA membership and/or units of APA (divisions, state associations, or APA governing units) the following 14 special reports:

1. An analysis of the Nixon Administration's 1974 Budget and Program Plans, with emphasis on implications for psychology.
2. A summary analysis (similar to No. 1) for distribution to all members of APA governance, boards, committees, and heads of academic departments.
3. A Federal Budget and Program article for the April 1973 issue of the *APA Monitor*.
4. A summary report on actions taken by APA to offset the effects of the 1974 Federal Budget and Program cuts.
5. An analysis of 20 National Health Insurance legislative proposals.
6. An analysis of proposed legislation on aging.
7. An analysis of proposed legislation on vocational rehabilitation.
8. An analysis of legislation extending the Public Health Services Act (S. 1136).
9. An analysis of legislation on student assistance.

10. An analysis of revenue sharing under the New Federalism.

11. Facts on Medicare and Medicaid.

12. Major health legislation in the 93rd Congress.

13. Facts and projections on professional standards review organizations.

14. An analysis of state associations' and divisions' legislative activities and interests—for the Committee on Legislative Affairs (COLA).

These reports either appeared as feature articles in the *APA Monitor* or were mailed directly to appropriate members of the Association's governing units.

In addition, the department prepared the regular monthly "Legislative Notebook" for the *APA Monitor* and provided staff liaison and logistic support to the transitory ad hoc Committee on Legislative Affairs and the ad hoc Committee on APA-CAPPS Relations, preparing the appropriate background or summary reports as required.

The department also organized and conducted the Fourth Annual APA Conference on Public Policy for Psychologists just prior to the Montreal Convention and either singly or with a Program Administrative Officer represented APA at numerous meetings of numerous other associations or coalitions thereof, including the National Association of Mental Health, the American Psychiatric Association, the Coalition for Health Funding, the Coalition for Mental Health Funding, the National Council of Community Mental Health Centers, and the Child Development Consortium. A leadership role was taken, with NAMH, in a state coalition effort which was instrumental in the extension of 12 health service acts in fiscal year 1974.

In a similar fashion, either directly or in a supporting role, the department provided APA representation in meetings with various Executive Branch officials, including the Deputy Secretary and Assistant Secretaries of DHEW, and officials of the Social and Rehabilitative Service, the Social Security Administration, and the National Institute of Mental Health. Discussions of APA interests were held with staff of individual legislators and committees and with members of Congress including Senator Hartke, Senator McClelland, Congressman Waldie, Congressman Ullman, Congressman Staggers, Congressman Burke, etc.

Presentations on psychology and government were also made in various forums, for example, Indiana Psychological Association, West Virginia Psy-

chological Association, Brookings Institution Seminars, and APA Convention programs.

A final note on External Affairs: Through its three departments and common administrative section, it handles most of the written and oral inquiries received by the APA from the general public. The number of letters rose substantially in 1973 and the sheer bulk of mail was somewhat overwhelming. Revised procedures for answering such a volume of mail now include greater reliance on referrals to divisions and to offices and departments within the Central Office, and on greater use of informational brochures. Personal replies, however, remained the most frequent chosen response to concerns and questions of the general public about psychology and the APA. In addition to its correspondence responsibilities, in 1973 External Affairs arranged public exhibits in the Central Office on the life and works of both Titchener and Wundt and a large APA exhibit at the Montreal Convention and arranged for APA representation at inaugural ceremonies for 12 college or university presidents.

Executive Office

The last and smallest office is that of the Executive Officer. Its staff consists of myself as Executive Officer, a secretary, the Personnel Officer, Robert Campbell, and a personnel assistant. This staffing description is slightly misleading in that two individuals located in other offices for administrative convenience report directly to and advise the Executive Officer on matters in their areas. These two are Jane Hildreth, Administrative Associate for Membership, and Harry Seymour, Public Affairs Officer. If you read this as reflecting my priorities, you will be more or less accurate. The first priority is the 36,000 members who constitute the real American Psychological Association as contrasted to the pseudo-Association of the Council of Representatives, the Board of Directors, and other governing units and the Central Office. The second priority is the Association's interactions with the world of American citizenry and the faces and positions we present to it, and the third priority is a feeling of responsibility for the approximately 165 employees of the Association.

PERSONNEL

The 1973 Proceedings (this issue, pp. 381-413) reports changes in the senior staff of Central Of-

fice. For graded staff there was, during this past year, a 23% turnover—well below par for the Washington, D.C., area. Our percentage of minority members employed now stands at 23%, up only slightly from last year but contrasting well with the 15% of three years ago. Thirty-six percent of the new hires during 1973 have been minority members, but a major problem remains in securing minority and women staff members at the upper management levels. Of 50 inquiries in response to an advertisement of professional staff positions in Central Office, only 1 was from a member of a minority group despite specific appeals to the Association of Black Psychologists and Psychologists for La Raza.

During 1973 the Central Office affirmative action plan was completed by the Personnel Office, with the assistance of the rest of the Central Office staff. It was praised with faint damns by the Board of Social and Ethical Responsibility for Psychology and with enthusiasm by the Board of Directors. A systematic review of all employee benefits was also made, resulting in a change in life insurance carriers (for a savings of \$5,000), the addition of a local health maintenance organization as a provider under the employee health plan, the addition of a cashable option on the retirement plan, the upgrading of the educational assistance program, and the standardization of policies on jury duty and maternity leave.

As for the Executive Officer activity during 1973, it is difficult to describe. The position description mentioned at the beginning of this report includes a variety of functions ranging from making contributions in the Association's name to worthy charities to preparing an annual budget, and also a handy phrase: "Will, directly or by delegation." This is then followed by everything I have reported on up to this point. Within the Central Office, aside from board and committee meetings, my major activity is carrying out the managerial functions involved in a \$6,000,000 operation with 167 staff members.

Externally, the major duty is serving as representative and spokesman for the Association in legislative and administrative, public policy, and interdisciplinary matters. Behaviorally, it involves a great deal of correspondence, telephone conversations, and scores of meetings or conferences. With a knowledgeable and competent staff, the legislative and administrative aspects are fairly straightforward: the staff prepares letters, documents, or testimony based on APA policies or positions and

the Executive Officer signs or orally presents the results. Presentations may be before Senate or House Committees or in conferences with legislative staff or administration officials. In almost every case the Executive Officer is accompanied by either an appropriate administrative officer from the staff or the Public Affairs Officer.

Public policy matters are somewhat more difficult because they frequently involve balancing the goals and objectives of the Association (see Article 1 of the Bylaws) and an assessment of the state of knowledge on the topic among psychologists with an apparent social good. It requires heavy reliance on the expertise of the membership as well as stated policies of the Association. It also necessitates holding one's disciplinary chauvinism in check.

The interdisciplinary interactions are the simplest and most enjoyable, involving as they do interactions with colleagues from other scientific and professional associations and agreements on common courses of action for mutual good.

Final Comment

That was the year that was for Central Office. With all its frustrations and turmoil it is now behind us and the staff is now gazing with cautious optimism at 1974. In my discussion of the several programs there was frequent reference to projects underway and the problems foreseen. I hope in my report to this body in 1975 I can announce all those projects completed and the problems resolved, but I doubt it.

Report of the Treasurer

ROBERT PERLOFF *Graduate School of Business, University of Pittsburgh*

This year's report can only begin with an expression of deepest gratitude to William McGiehee for his outstanding performance as APA Treasurer for five years. In December 1973, due to health considerations, he found it necessary to resign as our Treasurer. Fortunately, however, and with characteristic commitment to APA, Bill has agreed to serve on the Finance Committee this year, enabling us to achieve an orderly transition.

This report will highlight the critical aspects of our financial state, while future reports will seek prospectively to share with you ideas and philosophies and to solicit your ideas concerning the financial problems of and hopes for the Association.

For the second straight year the Association absorbed a deficit in 1972. The preceding Treasurer's report (McGiehee, 1973) predicted that "1972 will probably end the year with a deficit somewhere near \$125,000 [p. 293]." The year 1972 actually ended with revenues of \$5,387,891, expenses of \$5,508,229, and a deficit of \$120,338. Table 1 shows the main classifications of revenues and expenses for 1971 and 1972. Table 2 provides 1972 data by major program. A glimpse at APA's financial history for the last 22 years is furnished in Table 3, revealing that since 1968 APA's financial picture has been, at best, marginal and, realistically, deteriorating. Table 3 also demonstrates that the Association's expenses tend to double every five years. Of course, this growth is due partially to inflation, but it reflects, more importantly, expansion of APA itself as its membership widens and their demands increase.

Financial Condition

As stated in some prior Treasurers' reports, APA's financial condition (Table 4) appears very "healthy" as of December 31 of each year. For the most part, this state of affairs exists for two reasons: (a) A financial condition is representative of a point in time, and (b) the major part of the cash and marketable securities as of December 31 is temporarily held in custody as a result of advance payments of dues and subscriptions. These advance

TABLE 1

Revenues, Expenses, and Net Surplus (Deficit) for 1971 and 1972

	Year ending December 31	
	1972	1971
Revenues		
Member dues and fees (net of journal credit)	\$1,033,794	\$ 831,720
Journal subscriptions	2,131,036	2,026,155
Advertising	200,816	199,534
Other journal revenue	223,304	186,085
Sales of other publications and services	415,257	374,586
Registration fees	64,975	73,578
Exhibit space rental	33,718	53,600
Accreditation fees	69,300	71,660
Investments	89,441	82,884
Building revenue (non-APA tenants)	299,552	299,150
Grants and contracts	717,743	992,995
Other revenues	108,955	94,071
Total revenues	\$5,387,891	\$5,286,018
Expenses		
Personnel	\$2,068,591	\$2,021,674
Printing and mailing of publications	1,454,925	1,419,932
Editor's stipends and office expenses	216,044	182,948
Professional, consulting, and contractual services	334,125	316,924
Travel (other than boards and committees)	142,998	93,370
Boards and committees	192,779	185,726
Convention and placement local site expenses	43,246	57,070
Supplies, postage, telephone, other common office expenses	340,307	357,933
Building expenses	552,779	530,400
Other expenses	162,435	142,028
Total expenses	\$5,508,229	\$5,308,005
Net surplus (deficit)	\$ (120,338)	\$ (21,987)

TABLE 2

Revenues, Expenses, and Net Surplus (Deficit) by Major Program for January 1-December 31, 1972

Major program	Revenues	Expenses	Net surplus (deficit)
Services and activities (nonpublishing)	\$1,392,792	\$1,556,762	(\$163,970)
Communications (publications and biographical services)	2,903,486	2,925,671	(22,185)
Building operations (non-APA tenants only)	299,552	299,552	0-
Grants and contracts	619,757	619,757	-0-
Other (investments, mailing labels, other)	172,304	106,487	65,817
Total	\$5,387,891	\$5,508,229	(\$120,338)

1971	5,286	5,308	(22)	(.4)
1972	5,388	5,508	(120)	(2.2)
Total	\$43,639	\$42,891	748	1.7

Note. Numbers are given in thousands of dollars.

* Does not reflect grant activity.
* Does not reflect capital gain of \$148,858 on sale of property located at Sixteenth and O Streets, Washington, D.C.

TABLE 4

Comparative Statements of Financial Condition as of December 31, 1971 and 1972

	As of December 31	
	1972	1971
Assets		
Cash and marketable securities	\$2,767,521	\$2,425,781
Accounts receivable and pre-paid expenses	481,087	315,056
Other	99,256	97,274
Land, building, equipment (net)	3,902,842	3,590,811
Total assets	\$6,850,606	\$6,408,922
Liabilities		
Accounts payable	\$ 684,608	\$ 516,238
Building loan	2,253,296	2,029,799
Deferred income	2,782,917	2,280,765
Other	13,163	15,112
Total liabilities	\$5,734,014	\$5,171,912
Net worth	\$1,116,672	\$1,237,010
Total liabilities and net worth	\$6,850,606	\$6,408,922

payments, held as of December 31 of any given year, are shown in Table 4 as deferred income, but are consumed during the subsequent year's operations as the goods and services (for which advance payments were made) are delivered.

To illustrate the effect of the \$120,338 deficit in 1972 on APA's net worth, one has merely to glance at the net worth (Table 4) at the end of 1971 and 1972. As shown in Table 4, the Association's net worth declined by \$120,338 (the 1972 deficit), from \$1,237,010 at the end of 1971 to \$1,116,672 at the end of 1972. If this declination rate were to persist each year for the next 10 years, our net worth would be zero. The Association's net worth is essentially invested in nonliquid assets, namely, the headquarters building; therefore, it is not available to pay current bills. However, as stated above, the annual cycle of advance payment of dues and subscriptions provides the liquidity needed to pay current bills even in deficit years, provided these deficits are not excessive and not continuing year after year. Deficits cannot be absorbed indefinitely.

1. The first part of the document is a list of names and titles, including "The Hon. Mr. Justice" and "The Hon. Mr. Justice".

The manuscript is a collection of letters and documents, mostly from the 18th century. It is written in French and is a very good example of the handwriting of the period. The paper is aged and the ink is faded, but the text is still legible. The manuscript is a very important document for the study of the history of the French Revolution.

1. The first part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

2. The second part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

3. The third part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

4. The fourth part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

5. The fifth part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

6. The sixth part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

7. The seventh part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

8. The eighth part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

9. The ninth part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

10. The tenth part of the document is a list of names and addresses, which appears to be a directory or a list of contacts. The names are written in a cursive script, and the addresses are listed below them.

1. The first group was the "Young Men's Association" which was organized in 1852. It was the first of its kind in the city and was composed of young men who were interested in the study of the Bible and in the promotion of Christian work.

the Committee have no objection to the

By mail ballot of October 10, 1973, Council modified the above action to read in part:³ "and for officers other than the President-elect and the Executive Officer" The Committee on Structure and Function of Council was charged with preparing the necessary changes in the Bylaws and Rules of Council for consideration by Council at its January 1974 meeting. At its January 1974 meeting, Council voted that the following amendments to the APA Bylaws be submitted to the membership and the following revisions be made in Rules of Council:⁴

1. Article VII, Section 8.

The Recording Secretary shall be a Member of the Association, elected by the Council of Representatives, following nomination by the [Board of Directors] *Nominations and Elections Committee of Council*

2. Article VII, Section 9.

The Treasurer of the Association shall be a Member of the Association, elected by the Council of Representatives, following nomination by the [Board of Directors] *Nominations and Elections Committee of Council*

3. Article X, Section 1, third sentence (the section concerns election to boards and committees).

The [Board of Directors] *Nominations and Elections Committee of Council* [may nominate a single person for not more than one-third of the positions on any standing board or committee and the Board] shall nominate at least two persons for [at least two-thirds of the positions] *each position to be filled*.

4. New Rule of Council.

10.9.1. There shall be a Nominations and Elections Committee of Council that shall make nominations for (1) officers of the Association other than the President-elect and the Executive Officer, and (2) vacancies on standing boards and committees of the Association reporting directly to the Board of Directors and the Council of Representatives but excluding the Nominations and Elections Committee. The Committee shall consist of eight members, six of whom are members of Council at the time of election and elected by Council. The six Council members shall not be members of the Board of Directors at the time of their election. The President-elect with vote and the Executive Officer without vote shall also serve on the Committee. The six members elected by Council shall serve terms of three years, so staggered that two will be elected each year.

5. Revised Rule of Council.

30-6.1. Nominations for the various offices [to be filled by election of the Council] *that are elected by Council, other than the Board of Directors and the Nominations and Elections Committee*, shall be the final responsibility of the [Board of Directors] *Nominations and Elections Committee*. However, the nominations for members of committees reporting through any [other] Board *other than the Board of Directors and Council of Representatives* shall in the first instance be the responsibility of that Board. The Executive Officer shall call for suggestions of persons to serve on boards and committees from officers of divisions and state associations, and from chairmen of boards and

committees. The resulting list of names shall be available to the *Nominations and Elections Committee* and to the various boards when they are preparing nominations.

6. New Rule of Council.

30-6.9. Nominations to the Nominations and Elections Committee shall be by mail ballot distributed to members of Council. Each Council member will be allowed to nominate two candidates for each vacancy. Three persons will be nominated for each vacancy chosen in order of total nominations received.

Present Rules of Council would be renumbered accordingly.

J. On August 28, during the Convention, the Committee on Scientific Awards announced the APA Awards for Distinguished Scientific Contribution to Lee J. Cronbach, Brenda Milner, and Benton J. Underwood. The American Psychological Foundation's Gold Medal Award for 1973 was given to Harry F. Harlow. The Foundation's awards for Distinguished Contributions to Education in Psychology were presented to James E. Maas and Frank Joseph McGuigan. The Foundation's National Media Award was given to Gerald Jonas, for his two-part series entitled "Visceral Learning" which appeared in the *New Yorker* magazine. David Wechsler received APA's Distinguished Professional Contribution Award. Conrad L. Kraft was named the first winner of the Distinguished Contribution for Applications in Psychology Award.

K. The following report of membership changes during the year is presented as part of the report of the Membership Committee.

1. The Board of Directors elected 1,929 new Members and 977 new Associates, as of January 1, 1974, whose names were reported in the *American Psychologist*, 1974, 29, 135-145. In addition, 346 Associates were transferred to Member status as of January 1, 1974 (*American Psychologist*, 1974, 29, 146-147).

2. The Association was informed of the deaths of the following 158 members during the period November 10, 1972, through November 30, 1973:

Albert J. Aaronson
Henry F. Adams
Herbert M. Alexander

L. Upon recommendation of the Membership Committee and the Board of Directors, Council voted that the following amendments to the APA Bylaws be submitted to the membership: ¹

1. Article II, Section 8.

Associates who meet the standards for Member status will, upon application, [automatically] be advanced to Member on the January first next following the *deadline* date of application for such advancement.

2. Article XVIII, Section 7.

Any *Fellow, Member, or Associate* who has reached the age of sixty-five and has been a member of the Association for at least twenty-five years, or, *regardless of age or length of membership, who has been adjudged totally and permanently disabled*, shall be exempt from further payment of dues

If the Bylaws amendment is adopted, Rules of Council would specify that the determination of disability would be by an employer or by the Social Security Administration.

M. Upon recommendation of the Membership Committee, the Board of Directors voted approval for the issuance of certificates to Fellows, showing the year of election. The Board voted, further, that current Fellows be asked whether or not they wish to receive a certificate, and authorized Central Office to establish procedures and prices, if any.

N. Under New Business, at the Council's meeting on January 18-20, 1974, a motion was submitted by the Representative from Division 18 (Public Service) concerning the establishment of a new class of membership for retired members. The motion was referred to the Membership Committee for consideration and recommendation to Council at the 1974 New Orleans meetings.

O. The APA Representative to the Scientific Manpower Commission has for some time reported to Council through the Education and Training Board. That Board felt that it would be more appropriate for the Representative to report through the Board of Directors, inasmuch as the Ad hoc Committee on Human Resources is a committee of the Board of Directors. The Board of Directors concurred, and Council voted that Rule of Council 10-5.2 be amended accordingly.

P. The Board of Directors received a request from the American Association for the Advancement of Science asking that APA consider increasing its contribution to the support of the Scientific Manpower Commission. APA's current contribution is \$600. The Board postponed consideration of an increase until

more information is available on plans for the Commission.

This provision does not preclude notification to others as permitted by the Association's Bylaws and CSPEC's Rules and Procedures.

2. Amend Rule 60-3.1 as follows:²

In general, the Committee may furnish [upon request by] to the agencies listed in Article X, Section 5 of the Bylaws, the following: (a) the nature of the complaint; (b) the ethical principles involved; (c) the findings and recommendation of the Committee. Additional information concerning the evidence may be provided in the event that the requesting agency is itself concerned with violations of ethical principles [and it is able and willing to furnish the Committee with timely information about cases under scrutiny by the agency involving members of the APA. The agency shall also have] and has clearly established and acceptable procedures for handling ethical cases.

B. On recommendation of the Committee on Scientific and Professional Ethics and Conduct, the Board of Directors accepted the resignation of an APA member under ethics investigation for violations of the *Ethical Standards of Psychologists*, specifically, Principles 1, 1c, 2, 2a, 7, and 7c, and noted that his reapplication for membership should be subject to the provisions in Article II, Section 19, of the APA Bylaws.

C. At its meeting in May 1973, in a discussion of relations between boards and committees and Central Office, the Board of Directors reviewed the initial experiences of the new Board of Social and Ethical Responsibility for Psychology (BSERP) and its problems in establishing satisfactory working relationships with staff. What is the role of Central Office staff members working with a board or committee? Past Boards of Directors and the present one have maintained the principle that every Central Office staff member works for the Association as a whole and is responsible to the Executive Officer. Yet the staff member assigned as liaison to a board must provide the support it needs as effectively as possible. Problems arise when there is conflict between desires of a board or committee and administrative practices in Central Office or overall policies of Council or the Board of Directors. At times the staff member must be an advocate for his board or committee to the larger organization; at times he must remind the particular unit he assists that his activities are limited by other aspects of the organization.

BSERP is unique with respect to its role as a monitor of internal operations of APA as well as broader social and ethical problems. Moreover, BSERP is by its nature likely to be goading APA to action in areas where BSERP believes APA has been laggard. This places the staff liaison to BSERP in an especially difficult position.

In further discussion of BSERP at its meeting in June 1973, the Board of Directors expressed the view that BSERP should accept the responsibility for the work of committees in its area, as well as consideration of problems and issues referred to it through the usual channels.

Q. At its meeting on January 17, 1974, the Board of Directors voted to accept the recommendation of the Office of Programs and Planning and the Ad hoc Committee on Human Resources that APA publish a 1975 *Biographical Directory*, rather than a 1976 edition as voted earlier. It appeared that revenue from the initial publication of the *Consolidated Roster for Psychology* will not warrant the expense of collecting more nonmember data at this time. There will be a *Membership Register* in 1974. It was recommended further that outside sources of funds be sought to support the future continuation of nonmember data collection and statistical processing, with a study of the feasibility of publishing future consolidated rosters.

R. At its meeting in June 1973, the Board of Directors received an information report on the current status of negotiations with the Eastern Psychological Association and the Midwestern Psychological Association regarding the possibility of APA assistance in placement activities at their regional meetings. EPA found its present operation sufficiently effective, and MPA reported that it was conducting a feasibility study.

III. ETHICS, AND SOCIAL AND ETHICAL RESPONSIBILITY

A. At its meeting in February 1973, the Board of Directors received from the Committee on Scientific and Professional Ethics and Conduct (CSPEC) a series of suggestions for amendments to the Bylaws, the Rules and Procedures of CSPEC, and Rules of Council, designed to permit discretionary communication of information by CSPEC about members against whom charges have been filed. The proposed changes had been checked with Arnold and Porter (APA's counsel) and were unanimously recommended by CSPEC; they provide specifically for referral of complaints and information to state and regional psychological associations; to licensing and certification boards, without request; and for release of formal proceeding results to all concerned parties, for example, complainants, members, state and regional psychological associations, state licensing and certification boards, and the American Board of Professional Psychology. Further, the Bylaws amendments would permit APA committees and divisions to communicate among themselves in cases of alleged ethical violations. As reported under II-A-3 of these Proceedings, the membership approved the Bylaws amendments. Amendments to the Rules of Council are as follows:

1. Add the following sentence to Rule 60-2.5:

D. At its February 1973 meeting, the Board of Directors heard a report on the program to investigate discrimination policies of vendors to APA and voted to request the Executive Officer to communicate our concerns to other Washington-based scientific societies and to explore joint actions. BSERP had not yet developed criteria for what constitutes "essential services," nor substantive criteria for what would constitute compliance with APA's policies, but did report that it felt no doubts about continuing the project, urged collaboration with other associations, and had discussed the possibility of setting up a "test case" using media publicity.

At its meeting in January 1974, Council received an updated report of the APA Vendors' Program and was informed that BSERP, at its August 1973 meeting, had appointed a subcommittee to develop criteria for evaluating the data submitted by vendors.

E. At its meeting in February 1973, the Board of Directors heard a report from members of a subcommittee carrying out the Council mandate to investigate possible political misuse of medical and psychological rehabilitation procedures offered to returning Vietnam Prisoners of War (POWs). The subcommittee met with Pentagon members of the Department of Defense Task Force on Returning Prisoners of War of the Office of the Assistant Secretary of Defense for Health and Environment on February 16, 1973, and was received with friendliness but got little specific information. Plans were made to communicate with the presidents of the American Psychiatric Association, the National Association of Social Workers, and the American Orthopsychiatric Association concerning APA's experience, with the possibility of some kind of joint action if events warranted further endeavors.

At its meeting in November 1973, the Board was informed of a meeting held on November 10, 1973, between the BSERP Ad hoc Committee on the POW Issue and psychologists working for the Center of POW Studies in San Diego, California. The meeting was reported as having been fruitful and eventually cordial, after some initial questions about the implied mistrust of military psychologists resulting from the APA Council's resolution. A final report is expected by mid-1974.

F. Related to the general POW issue, the following resolution was adopted by Council at its January 1974 meeting:

RESOLUTION ON THE REHABILITATION OF YOUNG AMERICANS AFFECTED BY THE VIETNAM WAR

Recognizing that the psychological and moral burdens imposed on U.S. citizens by the war in Indochina—confronting them with profound divisions within their society, with anguish about the morality of actions taken in their names, with distrust of their national leadership, and with doubts about the justification for the sacrifices imposed upon them—weighed most heavily on the young men who were called upon to participate personally in the fighting in Indochina;

That the usual difficulty experienced by the veteran in the process of transition from military to civilian life, due to psychological traumata and other reasons, "had been markedly greater for the Vietnam veteran because of the controversial nature of the Vietnamese conflict and the rapid social-economic changes that occurred during his absence";⁴

That "studies conducted by the military and the Veterans Administration indicate that serious and prolonged readjustment problems exist in approximately one out of five new veterans, but to a lesser degree, were experienced by all";⁴

That Vietnam veterans as a group and their families have been receiving insufficient moral, psychological, and emotional support to enable them to come to terms with their experiences, to find employment, and to prepare themselves for the future;

And that many thousands of men who, for reasons of conscience, resisted the draft, or disobeyed military orders, or deserted, are now facing psychological problems associated with separation from their families, exclusion from their societies, and stigmatization as lawbreakers,

1. The Council of Representatives of the American Psychological Association endorses legislative and executive actions leading to:

a. Increased benefits for Vietnam veterans and improvements in the administration of such benefits, in order to assure that the educational, occupational, medical, and psychological needs of these men are adequately met, with real-dollar benefits at levels at least as high as those extended to World War II veterans;

b. A broadened definition of Service-related disabilities, which would give veterans the opportunity, on a wholly voluntary basis, to obtain treatment for psychological problems that do not require hospitalization or that manifest themselves only some time after their return home, and to obtain treatment for members of their families who play a significant role in their readjustment;

c. Freedom of choice for Vietnam veterans in contracting for psychological treatment, allowing them—whether they are still in service or out of service—the option of receiving payment for such treatment by civilian practitioners of their own choosing, if they feel that their needs cannot be adequately met by mental health personnel working within the military or the Veterans Administration; and

d. Active participation of Vietnam era veterans in developing and running the programs designed to serve their needs.

2. Council urges APA divisions and state and local psychological associations to establish registers of appropriately qualified psychologists whose skills in therapy, counseling, group leadership, or other psychological services might be useful in the rehabilitation of Vietnam veterans and war resisters, and who are prepared to devote some portion of their time to work with these men and their families, free of charge or at reduced rates. Such registers should be forwarded to Central Office so that they might be maintained centrally. Psychologists should be urged to participate in these programs, indicating both their skills and their time limitations, with the understanding that the existence of the registers will be publicized among prospective

⁴Quotations taken from a memorandum from the Department of Medicine and Surgery of the Veterans Administration, reproduced in part in the *Congressional Record* of October 12, 1973.

clients and that inquiries by such clients would periodically be referred to them

3. Council requests that the Board of Social and Ethical Responsibility for Psychology generate recommendations for just and humane policies designed to ease the psychological problems faced by war resisters and to help them reestablish themselves within the society.

4. Council urges relevant divisions, boards, and committees within APA to develop mechanisms and provide occasions for discussing and analyzing the psychological and moral implications of the Vietnam war and its effects on the American population and particularly on the generation most directly confronted with it.

5. Council requests that the APA Central Office and relevant boards and committees take active steps to promote and support legislative and executive actions, as well as activities within the profession, designed to implement the above proposals.

G. Council adopted the following Resolution on the Use of Psychiatric Diagnosis and Hospitalization to Suppress Political Dissent:

The Council of Representatives of the American Psychological Association reaffirms its resolution of December 1972, condemning the practice, wherever it may occur, of suppressing and neutralizing political dissenters by diagnosing them as mentally ill and committing them to mental hospitals. Council considers it the responsibility of individual psychologists to oppose such practices within the organizations in which they are employed and, if they do not succeed in changing the practices, to dissociate themselves from personal complicity in them. To implement this resolution, Council requests:

1. That the APA's representatives to the Assembly of the International Union of Psychological Science (IUPS) request the Executive Committee of the IUPS to place on its own agenda and on the agenda of the next meeting of the IUPS Assembly a resolution condemning the use of psychiatric diagnosis and hospitalization to suppress dissent and a plan to undertake an international survey of the prevalence of this practice;

2. That the President of the APA urge each member organization of the IUPS to express, through its representatives to the IUPS, its own concern with this issue and its interest in placing it on the agenda of the IUPS Executive Committee and Assembly;

3. That the Executive Officer and Board of Directors of APA, through the appropriate units within the APA Central Office and governing structure, gather available information on the prevalence of this practice in U.S. civilian and military organizations and explore the necessity and feasibility of a study within the United States, to be coordinated with a prospective international study; and

4. That the President of APA make contact with the President of the American Psychiatric Association, to inquire about the results of discussions with Soviet psychiatrists on practices in that country and to explore the possibility of joint action, if such is indicated, to protest Soviet practices.

H. Council received a number of information items concerning persecution of intellectuals in Chile and voted the following:

Because of concern for the safety of fellow social scientists and intellectuals in Chile, and because it has been announced that the right of safe passage for refugees will be

revoked after the beginning of February 1974, Council asks the Board of Social and Ethical Responsibility for Psychology, through staff, to take the following actions:

1. Make contact with the State Department urging the development of procedures permitting the entry of refugees from Chile into the United States;

2. Establish an ad hoc committee to ask APA members to set up a job bank, working in contact with the Job Clearinghouse of the Association of Latin American Studies, the National Council of Churches, and the American Friends Service Committee. Other professional associations should also be notified and urged to take similar action.

I. At the Council meeting in August 1973, a motion was introduced to establish an ad hoc committee on racism. Council voted to refer this matter to BSERP for recommendations to Council at the January 1974 meeting. The Board of Directors was informed that BSERP had been unable to consider the matter at its meeting in November 1973 but plans to take some action concerning this issue at its first 1974 meeting.

J. Council adopted the following Resolution on Discrimination Based on Social Class:

Recognizing past neglect of the problem of discrimination on the basis of social class, the Council of Representatives of the American Psychological Association affirms its commitment to working for the elimination of social class barriers to educational and employment opportunities in psychology; requests that the Board of Social and Ethical Responsibility for Psychology, in consultation with its Committee on Equal Opportunity in Psychology and other appropriate groups and individuals, propose mechanisms for APA study of and action on this issue to the Board of Directors for consideration at its meeting scheduled for June 28-29, 1974; and authorizes the Board of Directors to implement such proposals at the earliest opportunity.⁵

K. At its meeting in November 1973, the Board of Directors received a communication from the American Association for the Advancement of Science (addressed to Presidents of societies affiliated with AAAS), asking for support of its intent to prepare a statement of concern with respect to the treatment within Russia "of the distinguished physicist, Andrei Sakharov." The BSERP had been asked for its recommendation on the matter and strongly urged support. The Board of Directors voted to join with AAAS in its action, and our representatives to the AAAS were so informed.

L. At the meeting of the Board of Directors in August 1973, President Tyler reported on conversations she had had at the Vail Conference concerning APA responsibilities to minorities and the possibility of APA's funding of modest requests for help. The Board expressed its sympathetic understanding of the problem and its willingness to consider promptly any requests

⁵ This resolution stemmed from consideration of a memorandum addressed to Council from David M. Gray, entitled "A First Step in Eliminating Social Class Oppression," which had been referred to BSERP and the Committee on Equal Opportunity earlier.

for such funds recommended by the BSERP. The latter Board was encouraged also to consider such requests in an expedient fashion.

M. Upon recommendation of the Ad hoc Committee on the Status of Women in Psychology and the Board of Directors, Council at its August 1973 meeting voted to adopt the following new Rule of Council 60-13.1, establishing a continuing Committee on Women in Psychology, with the members of the Ad hoc Committee to be retained through 1974 as members of the continuing committee:

60-13.1. There shall be a Committee on Women in Psychology which shall concern itself with furthering the major purpose of the Association—to advance psychology as a science and as a means of promoting human welfare—by ensuring that women achieve equality as members of the psychological community, in order that all human resources be fully actualized. Its mission shall be that of functioning as a catalyst, by means of interacting with and making recommendations to the various parts of the Association's governing structure, to the Association's membership, and particularly to the Division of Psychology of Women, as well as to other relevant groups, such as the Association of Women in Psychology, the Federation of Organizations for Professional Women, and the National Council of Chairmen of Graduate Departments of Psychology. Specifically, the Committee will undertake the following priority tasks:

- The collection of information and documentation concerning the status of women;
- The continued development of recommendations and implementation of guidelines;
- The development of mechanisms to increase the participation of women in roles and functions of the profession;
- The ongoing communication with other agencies and institutions regarding the status of women.

The Committee shall consist of seven members, to be elected for staggered terms of three years. It shall report to Council through the Board of Social and Ethical Responsibility for Psychology.

N. At its March 1974 meeting, the Board of Directors received a draft of the "Proposal for Project Impact," to assist graduate departments of psychology in the education of their minority students, and voted to approve it in principle, authorizing the Executive Officer to seek support.

O. The following annual reports or minutes were received:

1. Annual Report of the Committee on Scientific and Professional Ethics and Conduct, including a summary of old and new cases before the Committee, for the period July 1, 1972, to June 30, 1973.

2. Minutes of the 1973 meetings of the Board of Social and Ethical Responsibility for Psychology.

3. Annual reports from the following committees reporting to BSERP:

a. Committee on Academic Freedom and Conditions of Employment, including a supplement providing

a comprehensive summary of cases reviewed during 1973.

b. Committee on Equality of Opportunity in Psychology

c. Ad hoc Committee on the Status of Women in Psychology.

IV. BOARD OF DIRECTORS

A. In accordance with Article VII, Section 3, of the APA Bylaws, the Board elected President Leona E. Tyler as its Chairman and President-elect Albert Bandura as its Vice-Chairman for 1973. For 1974, the Board elected President Albert Bandura as Chairman and Board member Richard C. Atkinson as Vice-Chairman.

B. At its meeting in November 1973, the Board voted that its provision for an Executive Committee of the Board be rescinded.

C. The Board adopted the following schedule of dates for its meetings in 1974: January 17, May 11-12, June 28-29, August 29 and December 6-7. A sixth meeting will depend on the dates of the 1974 adjourned meeting of Council, presumably in January 1975.

D. At its meeting in March 1973 the Board discussed the possible conflict felt by a Board member who may continue to represent a division on Council after election by Council to the Board of Directors. As a Board member, the orientation is toward APA as a whole; as a division representative, a special obligation is felt to represent the feelings of the division. To reduce this potential conflict the Board will recommend to newly elected Board members that they resign their positions as division representatives to Council when they assume their positions on the Board of Directors.

E. At its meeting in November 1973 the Board received with thanks an information report from the Ad hoc Committee on Archival History announcing that a second deposition of APA materials had been made to the U.S. Library of Congress.

F. At its meeting in November 1973 the Board decided to defer until its "retreat meeting" (May 11-12, 1974) a discussion of guidelines for responding to requests from individuals and groups wishing to appear before the Board at its meetings.

G. The Board discussed frequently during the year ways in which to improve communication with and from Council. President Tyler initiated a system of writing a special letter to Council after each Board meeting, reporting the highlights and providing more of the background discussion leading to decisions than ordinarily appeared in the Minutes. The Board also invited the chairman and chairman-elect of each of the

major boards to attend one of its meetings to present plans and programs, along with budget requests, for the coming year, and asked them to indicate which issues they wished emphasized at the winter meeting of Council. This procedure proved helpful, although hopes that board chairmen would indicate priorities in a way that would be helpful in preparing the APA's overall budget were not realized.

H. The following Board members were appointed as liaisons to the indicated boards and committees for 1974: Finance Committee, Robert Perloff; Policy and Planning Board, Herbert Kelman; Publications and Communications Board, John Lacey; Board of Convention Affairs, Donald Campbell; Board of Professional Affairs, John Conger; Board of Scientific Affairs, Richard Atkinson; Board of Social and Ethical Responsibility for Psychology, M. Brewster Smith; Committee on International Relations in Psychology, Leona Tyler; Committee on Legislative Affairs, Leonard Krasner; Ad hoc Committee on Human Resources, Kenneth B. Little.

V. DIVISIONS AND STATE ASSOCIATIONS

A. Council voted to approve the establishment of a new Division of Population Psychology (Division 34), effective January 1, 1974.

B. Council voted to approve the establishment of a new Division of Psychology of Women (Division 35), effective January 1, 1974.

C. Upon recommendation of the Committee on Structure and Function of Council and the Board of Directors, Council voted at its meeting in August 1973 to add the following sentence to Rule of Council 10-1.6:

If a Council Representative fails to attend a meeting of Council and does not arrange an alternate, the Recording Secretary will inform the Division or State Association of the failure of its Representative to attend the Council meeting.

(At the Council meeting in January 1974, there were only two division representatives and one state association representative who failed to attend or arrange for an alternate.)

D. At its meeting in November 1973, the Board of Directors voted approval of the submission of a grant application to the Social Rehabilitation Service for a research study by Division 22 (Rehabilitation Psychology).

E. At its January 1974 meeting, Council received a Special Report of the Policy and Planning Board on the Matter of Incorporation of Divisions. The action, after discussion, was to establish an ad hoc committee of Council, to be appointed by the incoming President, consisting of eight members, three to be from incorporated divisions, three from the other divisions,

with the Chairman of the Policy and Planning Board and a member of the Finance Committee serving as ex officio members. This committee was charged with clarifying the relationships of incorporated and unincorporated divisions to the APA, including the preparation of a list of possible division actions that might endanger the 501(c)-3 tax status of the APA. This action grew out of discussion of three specific recommendations, made by the Policy and Planning Board and supported by the Board of Directors (which had considered the report at its meeting on January 17, 1974), namely: (a) a division of the APA cannot commit or obligate any funds not currently available to that division or engage in any activities that might result in such obligation without prior consultation with the Board of Directors; (b) divisions shall account for their income and expenditures of funds to the APA on an annual basis as well as provide a statement of activities; and (c) divisions may not institute or participate in legal activities without prior approval of the Board of Directors.

During the discussion, the Executive Officer, in response to a question about why the concern had arisen, reported that APA's attorneys have determined that the integral nature of divisions to APA makes APA responsible for division actions, and, additionally, that APA's auditors have for some time argued that division income and expense information should be a part of APA's annual audit. Council was also reminded that at its Montreal meeting the question had arisen as to whether a division may appropriately engage in legal actions independent of APA (Division 29, Psychotherapy, had decided to join the CAPPS suit against Blue Cross/Blue Shield), that Council had voted to ask the Policy and Planning Board to study the matter, and that Council had asked that divisions contemplating legal actions delay them, pending the results of a study by Policy and Planning Board.

In summary, Council approved no specific recommendations on the matter, pending the report of the new ad hoc committee, to be available at the 1974 New Orleans meetings.

F. In a related action, upon recommendation of the Publications and Communications Board and the Board of Directors, Council voted at its January 1974 meeting that the following steps should be taken with respect to liability insurance for divisional publications:

1. The Board of Directors inform all divisions that the Association will attempt to secure liability insurance coverage on all known division publications (those publications not independently incorporated) and that each division must pay the insurance premium charged to its publication(s) by the insurance carrier (estimated at no more than \$25 for a newsletter; no more than \$75 for a journal).

2. The Board of Directors require divisions to submit a report to the Board of Directors as soon as prac-

ticable and annually (in January) thereafter concerning their publication operations. The report as a minimum would contain the following information for each division publication: (a) title and statement of editorial policy; (b) number of pages published; (c) total circulation and number of paid subscribers, if any.

Any major change in editorial policy or publication format must be reported to the Board of Directors.

3. A third recommendation, proposing a Bylaws amendment about nonjournal types of publication by divisions, was referred to the ad hoc committee established under Item V-E above.

G. In recognition of the increasing emphasis on the need for action in the public arena by organized psychology at the state and local levels, and in recognition of the increasing decentralization of important functions from the national organization to the state organization level, for example, ethics issues, Council at its Special Meeting in March 1973 voted that the Board of Directors publish a letter addressed to all APA members in the *APA Monitor* which identified (a) the increasing responsibilities and significance of state associations, (b) the relevance of state association activities to all psychologists, and (c) the need for support of state association activities through active membership by APA members. Further, in an effort to stimulate and support communication between state associations and APA members in a given state, Council voted that Central Office provide each state association, annually, up to three free copies of the relevant APA mailing list. (Both of these actions have been implemented.)

H. Further on the matter of state relations, Council voted at its Special Meeting that the Board of Directors explore, perhaps by the establishment of a special task force, and/or by referral to all APA boards, the interfaces between APA and the state associations. The purpose of this study would be to evolve recommendations intended to maximize the effectiveness of APA-state association interaction in the interests of the public and of American psychology.

I. Reports were received from the following divisions: 3 (Experimental Psychology); 9 (SPSSI); 12 (Clinical); 14 (Industrial and Organizational); 16 (School); 22 (Rehabilitation); 24 (Philosophical); 29 (Psychotherapy); and 33 (Mental Retardation).

J. Reports were received from the following state psychological associations: California, Delaware, District of Columbia, Montana, New Jersey, North Carolina, and Texas.

VI. ORGANIZATION OF APA

A. At its meeting in February 1973, the Board of Directors received a request from the Policy and Plan-

ning (P&P) Board for approval to seek funds for a month-long Conference on the Future of Psychology, to be held in 1973 under the P&P Board's direction (attendees to consist of members of the 1972 and 1973 P&P Boards). It was the P&P Board's judgment that their usual meeting schedule did not provide adequate time for consideration of long-range policies. The Board of Directors voted to ask the P&P Board instead to try to arrange a shorter conference that could be funded within its own resources. The Annual Report of the P&P Board for 1973 indicated that they had scheduled their second meeting for 1973 for six days with the major focus on the future of psychology.

B. At its meeting in August 1973, the Council voted to defer until its January 1974 meeting action on a motion to amend the Bylaws (Article XIX, Section 2) in such a way as no longer to permit the P&P Board to submit Bylaws amendments directly to the membership. The Board had noted that Council is free to submit its views as an accompaniment to P&P-proposed amendments, and its feeling that the P&P Board should be free (in terms of its original mission) to go directly to the membership. At its January 1974 meeting, Council defeated the motion as submitted. The P&P Board did go directly to the membership in 1973 with the amendment altering the conditions under which special meetings of Council can be called (see Item II-A-4, these Proceedings), reporting in its Annual Report that four responses were received from Council members in reply to P&P's request for comment prior to the vote.

C. By mail ballot September 28, 1973, the Board of Directors voted to appoint the P&P Board to serve as a task force to analyze issues involving psychology and its relationship to the field of health. At the Montreal meeting of the Board, there had been discussion of the need for such a task force, and it was decided that one should be appointed to report back in the fall of 1974. The P&P Board had expressed considerable interest in the project and informally had planned to undertake such an analysis. A motion submitted at the January 1974 meeting of Council that a Council task force be appointed to develop a position paper in this area was defeated.

D. At its January 1974 meeting, the Board of Directors reviewed a recommendation to be submitted to Council that would have recommended an amendment to the Bylaws to prevent the Executive Officer's voting as a Council member, voting to refer the matter to the P&P Board. The Council, however, defeated the motion without requesting referral. (As an elected officer, the Executive Officer is a nonvoting member of the Board and a voting member of Council.)

E. Under New Business at the January 1974 meeting, Council voted to refer to the Policy and Planning Board and to the Education and Training Board a motion that Council review the issue of master's-de-

gree-level training as a criterion for full membership in the APA.

F. At the August 1973 meeting of Council, a motion was introduced to provide that 30% of those members attending a Council meeting may order a roll call vote on any issue and order subsequent publication of the vote in the *APA Monitor*. This was referred to the Committee on Structure and Function of Council (CSFC), which recommended its approval, with a corresponding change in Rules of Council, as the current requirement is 50% under Robert's Rules of Order. The Board of Directors at its meeting in November 1973, however, recommended that the CSFC recommendation not be approved, feeling that a majority of Council is a reasonable percentage for a roll call vote and, further, that subsequent publication in the *APA Monitor* should not follow automatically but be voted upon in each instance. The Council, at its meeting in January 1974, discussed the matter fully and voted its approval of the original motion. A discussant suggested that written signed ballots might be an alternative to an oral roll call at times.

G. At the January 1974 meeting, a motion under New Business that Council meet three times a year for a minimum of two days at each meeting at four-month intervals was referred to the Committee on Structure and Function of Council.

H. At its December 1972 meeting, Council voted that an Ad hoc Committee on APA Organization be appointed, two members to be nominated by the Policy and Planning Board, two by the Committee on Structure and Function of Council, plus additional members they might wish to have join them. At its meeting in February 1973, the Board of Directors voted to appoint James Deese as the Chairman of the Ad hoc Committee and the following persons as members: George W. Albee, Marcia Guttentag, Edwin B. Newman, Lyman Porter, and John Stern.

At its meeting in August 1973, Council received a "Preliminary Report for Discussion" from the Ad hoc Committee, voting to discuss it in Committee of the Whole. The report suggested a decision-making structure based on participation by selected Council members as members of substantive boards concerned with four major roles of psychologists, the boards to be those of professional affairs, scientific affairs, educational affairs, and psychology in public policy (the Committee had not yet come to conclusions concerning the areas of publications and the convention). An Executive Board of Council would be composed of members of Council selected from each of the substantive boards in addition to the Association officers. Each of the boards would presumably have committees, and there would be a system of advisory and operating committees to assist the Executive Board to direct Central Office activities, plus a "watchdog" committee of

Council to monitor the implementation of policy determinations made by Council.

Straw votes and comments indicated the following opinions of Council: (a) the plan could provide a better structure for setting priorities; (b) the plan should be submitted in parts for action, so that Council (and other groups and individuals considering the report) could indicate approval of some, but not all, of the recommendations; (c) the hope that there could be definite recommendations by the January 1974 meeting; (d) the Committee should consider the possibility of member dues allocations to the areas covered by the four boards, plus a fifth for "housekeeping" funds; (e) the relation of divisions under the proposal should be considered as more important than the Committee was reported to feel; and (f) a general observation that the plan appeared more viable than previous proposals for changes in APA structure.

Council was informed that the Finance Committee and the Board of Directors had referred to the Ad hoc Committee a letter from the Ad hoc Committee on Dues Structure, constituting its final report. Council received a copy of the letter for its information.

At its meeting in January 1974, the Board of Directors received the Final Report of the Ad hoc Committee on APA Organization and after extended discussion voted not to recommend approval of the recommendations of the Committee, but to recommend that the report be referred to the Policy and Planning Board for consideration as part of its continuing review of APA organization. The Board voted, further, to discharge the Ad hoc Committee with thanks for the devoted work involved in preparation of its recommendations and with sympathetic awareness of the frustrations involved in any effort to bring about major restructuring of APA.

The Board noted that in the recent history of APA the Council has consistently rejected proposals for major changes in APA structure. The fact that the issue keeps arising suggests that there are real and continuing problems. In discussion of this plan in Council, attempts should be made to identify specific, less-sweeping changes that might improve APA functioning. The Board decided to discuss the general matter at its retreat meeting in May 1974, including the development of specific changes that might be recommended under the present structure. It was also pointed out that several changes already made in the last year may make the apparent problems less forbidding—the establishment of a Nominations and Elections Committee of Council; the establishment of a Committee on Legislative Affairs—and that time should be taken for evaluation.

When Council received the Final Report of the Ad hoc Committee, along with comments from the Board of Directors, at its January 1974 meeting, it voted to concur with the Board's recommendation that the re-

port be referred to the Policy and Planning (P&P) Board, with the further request that the P&P Board report to Council at the 1974 New Orleans meetings (with adequate time provided for full discussion), considering also a motion (not adopted by Council) from a Representative from Division 3 (Experimental) that additional alternatives be presented by the P&P Board, including an earlier plan for federation. The P&P Board Chairman asked for comments from Council members, and the Chairman of the Ad hoc Committee informed Council that he would forward all relevant materials from his Committee to the P&P Board. The Ad hoc Committee was discharged with thanks.

I. At its "retreat meeting" in May 1973, the Board of Directors discussed current conflicts between some scientific and professional groups within APA, noting that the organization of one faction also forces other factions to organize. Also discussed was a possible need to call Council's attention to the more controversial issues coming up on the Council agenda and to generate more interest by divisions and state associations in APA-wide affairs.

J. The following reports were received:

1. Annual Report of the Policy and Planning Board.
2. Special Report of the Policy and Planning Board on the Matter of Incorporation of Divisions.
3. Annual Report of the Committee on Structure and Function of Council.
4. Final Report of the Ad hoc Committee on APA Reorganization.

VII. PUBLICATIONS AND COMMUNICATIONS

A. At its meeting in February 1973, the Board of Directors received with thanks and approved in principle a statement of 1973 goals for the Publications and Communications Program, with the understanding that the Publications and Communications (P&C) Board and its Communications Committee will approve goals, review specific elements, and establish priorities. The Board also discussed changes in journal operations proposed by the P&C Board, noted certain reservations expressed by the Board of Scientific Affairs and staff, and referred the proposals back to the P&C Board.

B. At its meeting in May 1973, the Board of Directors authorized an increase of \$17,000 in the 1973 Budget of the P&C Board to meet expenses due to changes in editors and excessive backlogs accumulated by the outgoing editors.

C. At its June 1973 meeting, the Board of Directors was informed that the 1974 Preliminary Budget for the P&C Board included funds for page increases to facilitate holding the publication lag to 12 months for

all journals and to ease the transition period for the five journals whose editorships are changing. Editors will be asked, strongly, to agree to stay within their page allotments and to keep the lag down. The Board was also informed that the 1974 Preliminary Budget for the P&C Board included an increase in funds over 1973 for office expenses for editors, reflecting the overlapping expenses of incoming and outgoing editors for four journals.

D. The Board, upon recommendation of the P&C Board, approved the concept of a program to conduct exploratory and management studies of the journals, *Psychological Abstracts*, and such other products and services as the P&C Board may determine as necessary to maintain the quality and economic integrity of the APA publications and communications services. The Board did not approve, however, increasing the P&C Board 1974 Budget by the recommended amount. In view of budgetary stringencies, the Board doubted that the P&C 1974 Budget would permit as extensive a program as envisaged by the P&C Board. After reviewing anticipated revenues and expenditures, the Board of Directors, as of June 1973, set a goal for 1974 of \$85,000 or more of revenue over expense for the publications and communications activity.

E. The Board received with interest a report from the P&C Board of proposals planned for the *Journal of Experimental Psychology (JExP)* and the *Journal of Comparative and Physiological Psychology (JCPP)*. The P&C Board voted that the *Journal of Experimental Psychology*, beginning with 1975, will be divided into four sections under the general title of *JExP*, with each section edited by an independent editor appointed by the P&C Board, but with all four editors comprising the Board of Editors of *JExP*. The sections, which may be subscribed to independently, will be: *JExP: General*; *JExP: Learning and Memory*; *JExP: Perception and Performance*; and *JExP: Animal Behavior Processes*. Beginning in 1975, the P&C Board voted to move experimental studies of animal behavior processes, which have as their main focus the advancement of general behavior theory, from the *JCPP* and to continue *JCPP* as a general journal of physiological and comparative psychology.

F. At its May 1973 meeting, the Board of Directors, at the request of the P&C Board, approved increases in subscription prices to the amounts listed below, beginning in 1974:

JOURNAL	MEMBER	NONMEMBER
<i>Contemporary Psychology</i>	—	\$15
<i>Comparative and Physiological Psychology</i>	\$25	\$60
<i>Counseling Psychology</i>	—	\$15
<i>Psychological Review</i>	—	\$15
<i>Developmental Psychology</i>	—	\$30

G. At its November 1972 meeting, the Board of Directors had voted to establish a Task Force on the

American Psychologist, composed of representatives of the P&C Board, the Board of Directors, and staff. At its January 1974 meeting, the Board received with thanks and appreciation the report of the Task Force, voting approval of its recommendations, as follows:

1. The *AP* continue, as it has in the past, to be upgraded editorially, but that a more "popular" type format and content not be adopted.

2. Agreed with the Task Force that many of the APA materials obligated by the Rules of Council, which are presently contained within the pages of the *AP*, should continue to be published in *AP*, but that some attempt be made to present them separately, placing a higher emphasis on the substantive articles. Staff has agreed to provide the Task Force with the necessary background information for a plan of action, to be forwarded to the Board for consideration at a later time.

The Board noted that at its November 1973 meeting it had voted to move regional association proceedings and APA's convention program proceedings to the *Journal Supplement Abstract Service*.

3. It is essential that the editorship remain within the Central Office, with the Executive Officer serving as Editor and the Board of Directors as an editorial advisory board.

4. The *AP* should continue to be under the aegis of the Board of Directors, getting appropriate advice from the P&C Board, treated separately from the other journals for purposes of budget analysis and page allotment deliberations. The Board of Directors is charged with taking a more active role in guiding *AP* policies, and the *AP* should be subject to annual policy review by the Board of Directors.

5. The *AP* should continue to be included as part of Association dues and the price continue to be governed by the economics of the Association.

H. At its June 1973 meeting, the Board of Directors was informed that its Executive Committee had affirmed the decision of the Executive Officer that the *Journal Supplement Abstract Service* (JSAS) be included on the 1974 dues statement as an available publication.

I. At its meeting in November 1973, the Board had asked staff to investigate the costs of libel insurance for all of APA's journals. (APA carries such insurance for the *American Psychologist*, *Psychological Abstracts*, and the *APA Monitor*.) Investigation proved that such insurance would cost around \$90 per year for each additional journal. At its January 1974 meeting, the Board voted that libel insurance should be purchased for *Contemporary Psychology* but was not needed for the other journals. (See Item V-F, these Proceedings, for related actions with respect to liability insurance for division publications.)

J. Upon recommendation of the P&C Board, and of the Board of Directors, Council voted at its January

1974 meeting that the following wording be substituted for the present Rule of Council 70-10.1 concerning occasional publications (separates):

The American Psychological Association shall publish and disseminate those books, pamphlets and other materials that are necessary to inform: (a) the psychological community or (b) the public about psychological standards, scientific and professional advances, education and training opportunities, and such other information that meets the following criteria:

1. Is consistent with the objectives of the Association and furthers the purposes of APA as a not-for-profit organization;

2. Has excellence of content as attested to by independent editorial reviewers;

3. Is generated within APA, its boards or its committees, or is submitted, commissioned, or selected for publication or dissemination, and in any case is approved by a relevant board of APA;

4. Performs a communications function that would not be accomplished at all, or accomplished as well, by the commercial sector.

This program shall be planned and managed in such a manner as to recover its cost. There shall be a committee of the Publications and Communications Board to be concerned with advising the Executive Officer on overall goals and guidelines for the separates program.

Final determination of what is acceptable, including the alternative of rejection in whole or in part, in any pamphlet, book, or report offered publicly by the Association shall be made by the Executive Officer, except that the Council of Representatives may vote, on recommendation of the Board of Directors, to set up some alternative means of editorial control. In this latter case, it shall be the responsibility of the special editor to consult with the Executive Officer and the Managing Editor before giving his final approval to the document in question.

K. Upon recommendation of the P&C Board and the Committee on International Relations in Psychology, the Board of Directors at its June 1973 meeting endorsed APA's application for APA membership in the International Council of Scientific Unions-Abstracting Board.

L. The following reports were received:

1. Annual Report of the Publications and Communications Board and of the following committees and representatives reporting to the Board:

a. Communications Committee.

b. Council of Editors.

c. APA Representative to the National Federation of Abstracting and Indexing Services.

VIII. CONVENTION AFFAIRS

A. At its December 1972 meeting, the Board of Directors directed the Convention Manager to continue negotiations toward a more favorable cost arrangement with the San Francisco hotels and to report his finding to the Board. The Convention Manager reported at the February 1973 meeting of the Board that

negotiations were successful; therefore, there was no need to change the plans for San Francisco to be the site for the 1977 Convention. At its June 1973 meeting, upon recommendation of the Board of Convention Affairs, the Board of Directors approved Toronto, Ontario, Canada, as the site for the 1978 Convention. (The sites for 1974, 1975, and 1976 are New Orleans, Chicago, and Washington, D.C., respectively.)

B. At the January 1974 meeting of Council, a straw vote was taken which indicated the willingness of Council to have the Board of Convention Affairs include the city of Las Vegas, Nevada, in its consideration of western convention sites. There is a policy to hold APA conventions on the west coast every three or four years, and the Convention Caucus, informed of the difficulties in finding adequate cities, agreed that Las Vegas, with its many reasonably priced hotel rooms and good meeting facilities, should be considered.

C. Under New Business at the January 1974 meeting of Council, a resolution was submitted by the Representative from Division 22 (Rehabilitation) concerning convention facilities for the disabled. Council concurred with the action of the Board of Directors in referring the resolutions to the Board of Convention Affairs (BCA), noting that the BCA has also been concerned about the problem of architectural barriers that cause difficulty for the physically handicapped and has made it a part of the convention-planning activities.

D. At its November 1973 meeting, in its discussions of ways in which anticipated deficits in the 1974 Budget might be reduced, the Board of Directors voted that the Budget for the convention be revised to show a net gain to the Association of \$50,000. The Board noted that such a change would almost certainly involve increased convention registration fees.

E. Council, at its meeting in August 1973, had voted to increase convention registration fees to \$15 for members and \$25 for nonmembers (the fees charged on a temporary basis for the Hawaii and Montreal meetings), with no fees for students or dues-exempt members. At its meeting in January 1974, however, Council approved the recommendation of the Board of Directors that 1974 convention registration fees be established as given in the table below, and that Council Rule 150-2.2 be revised to delete references to dollar amounts, with a new Rule 150-2.3 authorizing the Board of Directors to set fees annually after recommendation from the Board of Convention Affairs.

	1974 FEES		
	CURRENT FEES	ADVANCE	ON-SITE
Members *	\$15	\$20	\$25
Nonmembers	25	30	35

There had been an earlier recommendation that a small fee would be charged for student categories, but

* Dues-exempt members and students shall be exempt from convention registration fees.

this was disapproved by the Board of Directors at its January 1974 meeting and concurred in by Council. Helpful to the Board was a staff analysis of convention fees in 1973 and data concerning fee practices of similar associations.

F. The following reports were received:

1. Annual Report of the Board of Convention Affairs and of the following committees reporting to the Board:

- Committee on Films and Other Media.
- Operations Committee.
- Committee on Program Innovations.
- Committee on Research and Evaluation.

IX. EDUCATIONAL AFFAIRS

A. During the year, the Board of Directors took the following actions with respect to communications and recommendations submitted by the Education and Training (E&T) Board:

1. At its February 1973 meeting, was informed that the E&T Board had appointed Robert Schaefer, Professor of Education and Dean of Teachers College, Columbia University, as a "knowledgeable layman" to the Committee on Accreditation, in response to a request from the Board of Directors.

2. At its February 1973 meeting, received with thanks and commendation a near-final draft of the Proposal for a Secondary School Curriculum Development Project on Human Behavior.

3. At its May 1973 meeting, the Board discussed at length the extent to which the Association should take a direct hand in the education of future psychologists. Under this broad heading it considered—without conclusions—such issues as:

a. Whether or not APA should set up a college of its own and if so at what level, undergraduate, graduate, or postdoctoral; how and from where resources could be secured for such a venture; the relationship of such an institution to existing agencies or universities.

b. Patterns of support for graduate training most appropriate in terms of educational values, political realism, social needs, disciplinary needs, and desires of students for training; whether or not support should be on an individual or institutional basis; the appropriateness of support when jobs are beginning to diminish, the possibility that the apparent shortage of positions for psychologists is an artificial result of governmental policies; and the possibility that continued production of psychologists would force the development of new careers utilizing their skills.

c. The need for continuing assessment of education in psychology; the possibility that APA's major impact in this area might come through constant up-

grading of, for example, the Area Examinations in Psychology of the Educational Testing Service and a national assessment of achievement of psychology. Related to this last was discussion of whether such assessment should be restricted to the undergraduate and graduate levels. The Board asked that the attention of the E&T Board be called to the national-assessment-in-psychology idea and noted that several psychologists were experts in the area and could serve as consultants. It also noted that the general idea might be of interest to such pandisciplinary organizations as the American Council on Education, the Social Science Research Council, and the American Council of Learned Societies.

4. At its June 1973 meeting, the Board voted concurrence with the E&T Board's recommendation that a subscription charge for *Periodically* not be initiated.

5. At its June 1973 meeting, the Board concurred in the E&T Board's suggestion that other boards be informed of the E&T Board's practice of open advertising for membership on its committees and on that Board, via notices in the *APA Monitor*.

6. At its June 1973 meeting, the Board voted to approve a full-time staff position in the Office of Educational Affairs to develop and monitor APA activities in the area of continuing education, but contingent upon obtaining external support for the position, in view of budgetary stringencies. At its August 1973 meeting, the Board received a communication from the Chairman of the E&T Board, requesting an increase in the budget of that Board in order to secure the services of "a cognizant APA member who has a background in the area of continuing education, to be commissioned to review the APA's needs and potentials in continuing education and, in particular, to seek ways and means for supporting such activities." The Board voted to reaffirm its action of June 1973 and expressed the view that preparation of a proposal seeking funds could be done within the E&T present budget.

B. At its August 1973 meeting, the Board received a communication stemming from the Vail Conference concerning the composition of the Follow-up Commission to be established to implement the conference recommendations, voting to endorse the recommendations of the Conference for the Commission. Discussion of the Vail Conference recommendations themselves, by the Board of Directors and Council, had not yet occurred, formally, as of the January 1974 meetings.

C. At the November 1973 meeting of the Board, President Tyler reported on a meeting held with representatives of the Black Students Psychological Association (BSPA) on September 27, 1973. The Board voted to ask the Office of Educational Affairs to consult with BSPA and to arrange liaison on ways of improving information collection and dissemination from and for minority graduate students. Further, the Board voted that BSPA not be required to repay the loan made as of July 1, 1970, to assist in the maintenance of a Washington office for a three-year period.

D. The Council, upon recommendation of the E&T Board and the Board of Directors, voted approval at its January 1974 meeting of changes in Rules of Council 90-2.1 and 90-3.1 to increase the size of the Committee on Accreditation from six to nine members, and to update (from August 1971 to January 1973) the references to procedures and criteria now in force. Action was delayed on a recommendation to substitute the word "professional" for "clinical, counseling and school" in defining the programs to be accredited, pending further review by the E&T Board. The use of "professional" was deemed ambiguous.

E. On recommendation of the Board of Directors, Council adopted at its January 1974 meeting the following schedule of accreditation fees for 1974-1975:

UNIVERSITY PROGRAMS	FEE
Annual Accreditation Fee (first program)	\$300
Annual Accreditation Fee (second program)	150
Visit Fee	700
Application Fee (per program)	300
Initial Visit Fee (per program)	700
INTERNSHIP PROGRAMS	FEE
Annual Accreditation Fee	\$375
Application Fee	300
Initial Visit Fee	400

F. The following reports were received:

1. Annual Report of the Education and Training Board and reports from the following committees and other bodies reporting to the Board:

- Committee on Accreditation.
- Committee on Pre-College Psychology.
- APA Visiting Psychologist Program.
- APA Visiting Scientist Program.
- Ad hoc Committee on the 2-Year College.
- Task Force on Issues of Sexual Bias in Graduate Education.
- Resolutions and Proposals of the National Conference on Levels and Patterns of Training in Professional Psychology, Vail, Colorado, July 25-30, 1973.

X. PROFESSIONAL AFFAIRS

A. The Board of Directors took the following actions with respect to recommendations and other communications from the Board of Professional Affairs (BPA) during the year:

1. At its February 1973 meeting, voted to approve publication of "Guidelines for Psychologists Conducting Growth Groups" in the *American Psychologist* at an early date. (See *American Psychologist*, 1973, 28, 933.)

2. At its February 1973 meeting, voted to accept an invitation to join the National Consortium for Child Mental Health Services. Other members of the Consortium are: American Academy of Child Psychiatry,

American Association of Psychiatric Services for Children, American Association for Children's Residential Centers, American Association on Mental Deficiency, American Medical Association, National Congress of Parents and Teachers, National Association of State Mental Health Directors, and Society of Professors of Child Psychiatry.

3. At its February 1973 meeting, was informed that APA has been appointed *amicus curiae* in the matter of *Morales v. Therman*, a class action on behalf of juveniles committed to residential training schools in the State of Texas. As it did in *Wyatt v. Stickney*, APA is joining with the American Orthopsychiatric Association, the Center for Law and Social Policy, the American Association on Mental Deficiency, and the Civil Liberties Union as *amicus curiae*. Also participating are the Child Welfare League and the National Council on Crime and Delinquency.

4. At its February 1973 meeting, received a recommendation concerning possible opposition to a proposed revision by the Supreme Court in the rules of evidence for federal courts, voting to defer action pending additional information.

5. At its February 1973 meeting, was informed that the Accreditation Council for Facilities for the Mentally Retarded (AC/FMR) had approved the admission of the APA as a Council member, and authorized the payment of the \$3,000 annual contribution, requesting also that the BPA name two Councillors to represent the APA on AC/FMR. Membership on the Council was approved by the APA Council in 1969.

6. At its February 1973 meeting, authorized increases in the 1973 Budget for BPA from \$20,000 to \$30,000, the additional funds requested for the Committee on Health Insurance, the Task Force on Regional Review Committees, liaison responsibilities with the American Board of Professional Psychology and the American Association of State Psychology Boards, and for a Division Presidents Liaison Meeting.

7. At its May 1973 meeting, in response to a request from the Office of Child Development (OCD), approved initial submission of a proposal to provide part-time consultation by APA members to OCD in developing a strategy for providing mental health services to Head Start children (with consultation with relevant divisions).

8. At its June 1973 meeting, informed that the Council of National Organizations for Children and Youth, to which APA belongs, had been replaced by the National Council of Organizations for Children and Youth (NCOCY), voted to approve membership in NCOCY, and authorized the Executive Officer to appoint a representative.

9. At its June 1973 meeting, received a report of a Summer Intern Project on Social Responsibility, administered under the direction of Gottlieb Simon.

10. At its June 1973 meeting, was informed that Ralph Nemir had been hired to function in the capacity of a state legislation specialist and to provide informal liaison with state associations on many matters, including revenue-sharing programs.

11. At its June 1973 meeting, the Board discussed a proposal from Lloyd Humphreys that the Association study the advisability—from the public's point of view—of the inclusion of psychotherapy in medical insurance contracts, policies, or programs. Opinions varied as to the merits of his arguments, but the matter was referred to BPA for its advice and recommendations, with consideration of the broader context of psychology's role as a health profession. Learning at its November 1973 meeting that BPA had referred the matter to the Committee on Health Insurance, the Board voted that the proposal also be referred to the Policy and Planning Board for consideration in its role as a task force to develop a position paper on psychology and health. (See Item VI-C, these Proceedings.)

12. At its November 1973 meeting, the Board voted to request the Board of Directors of the American Board of Professional Psychology (ABPP) to establish a National Registry Council as outlined in the recommendations of the Ad hoc Coordinating Committee for the National Registry of Health Service Providers in Psychology, with the provision that rules and regulations promulgated by that Council receive prior review from BPA before implementation, as well as any changes in such rules and regulations. There shall be no financial obligation nor expenditure by APA in direct support of this task. The Board was informed that ABPP was willing to undertake this activity, and that listings of individuals in the Registry would be on a voluntary basis.

13. At its November 1973 meeting, the Board was informed that the Center for Law and Social Policy, the American Psychiatric Association, and the American Orthopsychiatric Association planned to initiate litigation to establish minimum standards for alternative facilities for mental patients in St. Elizabeths Hospital in Washington, D.C. Upon recommendations from the Task Force on Standards for Service Facilities and with consultation from APA's attorneys, the Board authorized the Executive Officer to indicate APA's interest in joining the suit, with formal approval contingent upon review of the actual proposed complaint. (Secretary's note: The suit was filed on February 14, 1974, with APA and the American Public Health Association as additional parties to those listed above.)

B. John Spiegel, President-elect of the American Psychiatric Association, was present by invitation during part of the Board's meeting in November 1973, to discuss mutual problems and proposed solutions facing the two APAs in a wide variety of areas. Similarities were marked. Plans were made for Albert Bandura, President-elect of the American Psychological Association,

tion, to attend a future meeting of the American Psychiatric Association's Board of Trustees.

C. At its December 1972 meeting, a resolution had been submitted to Council to establish a Task Force on Child Development. The resolution was referred to the Board of Professional Affairs, which considered the matter during 1973 and reported to the Board of Directors and Council in January 1974 that in view of existing policy statements and position papers a new task force is not indicated. BPA provided copies of three documents: BPA Statement on the Report of the Joint Commission on Mental Health of Children; Position Paper on Children and Youth, by the APA Ad hoc Committee on Children and Youth; and a Position Paper on the 1970 White House Conference on Children and Youth, from the Section on Clinical Child Psychology of Division 12 (Clinical).

D. Upon recommendation of BPA and the Board of Directors, Council voted at its January 1974 meeting to discharge the Committee on Relations with Other Professions and to amend Rules of Council accordingly. Council concurred with the reasons offered by BPA: policy coordination and continuity are becoming increasingly important; Central Office staff can provide interprofessional cooperation more promptly and effectively than can a committee.

E. Upon recommendation of BPA and the Board of Directors, Council voted at its January 1974 meeting to establish a continuing Committee on Professional Standards Review, with the following mission and composition incorporated as a new Rule of Council:

There shall be a Committee on Professional Standards Review which shall have the purpose of recommending policy and providing guidance for the operation of state, local, and regional professional standards review committees. The committee shall stimulate the development of state, local, or regional PSRC's and maintain up-to-date guidelines for their operation.

The committee is also charged with responsibility for developing workshop programs at the APA annual conventions and at various regional conventions in order to educate psychologists on matters relating to professional standards review. The committee will further provide a clearinghouse function and will maintain a file of case summaries which it will be provided by state, local, or regional review committees.

The committee is also charged with the task of noting problem areas which are developing and of alerting the Board of Professional Affairs to these matters.

The committee shall consist of seven persons from throughout the United States, including two public representatives, and shall be elected for staggered terms of three years.

The committee shall report to Council through the Board of Professional Affairs.

F. At its Special Meeting in March 1973, Council voted that a proposal be developed for a continuing evaluative research effort to develop social indexes to measure the effects of funding cuts on psychological

services, research and education generally, and, additionally, to track the processes of government which may stimulate or inhibit the initiatives of organizations involved in these activities. The matter was referred to the Board of Professional Affairs, the Board of Scientific Affairs, and the Education and Training Board, with BPA to act as coordinator pro tem, for the purpose of ensuring the writing of a proposal, with budget, for consideration by Council at its Montreal meetings. BPA recommended to the Board of Directors in June 1973 that such a social indicator study not be undertaken by APA (too big a project for APA's inadequate funds, etc.), and that consultation with BSA and the E&T Board had not yet taken place. The Board asked that the requested consultation be pursued by BPA and a new recommendation with more details be prepared for later consideration. The Board was informed at its November 1973 meeting that the Chairman of BPA was in the process of consulting with the Chairmen of the E&T Board and BSA.

G. In lieu of an annual report, BPA submitted copies of the Minutes of its meetings held on February 15-16, 1973; May 4-5, 1973; and October 11-12, 1973. No reports were submitted by the committees and task forces reporting to BPA.

XI. SCIENTIFIC AFFAIRS

A. At its meeting in February 1973, the Board of Directors received reports and communications from the Board of Scientific Affairs (BSA), the Education and Training Board, and staff with respect to impending cuts in federal support for training, research, and service in psychology. The Board also received a communication from the Chairman of BSA about anticipated changes in the processes by which science and science-related decisions are to be made in the federal government, for example, diminution of the role of the peer review system; demise of the President's Scientific Advisory Committee. The following recommendations were made: (a) the Board of Directors should develop an effective expression of concern relative to the loss of funds for training, research, and service, this expression of concern to be presented as the basis of a coordinated mailing from APA members to their senators and congressmen; (b) the Central Office staff should develop an information package concerning the changes in funding patterns, detailing current changes in funding patterns, detailing current changes and their implications; (c) APA should develop a system to gather and disseminate information on current funding problems and on alternative ways of coping with funding for training, research, and service; and (d) the Steering Committee for the Conference on Levels and Patterns of Professional Training should be asked to

include the problem of reduced funding on the agenda for the forthcoming conference.

The Board was informed that Central Office had already developed an information package for department chairmen and individuals in the APA governing structure, and was actively involved in facilitating communication among those primarily concerned with coping with the changes. An article for the *APA Monitor* had been prepared, and APA Central Office staff was in communication with other national associations similarly affected by the budget cuts. The Office of Policy Research was collecting data relevant to the case for continued funding, as well as preparing projections of future societal needs for psychologists. The Ad hoc Committee on Human Resources had been asked to explore as rapidly as possible additional sources of information and data relevant to the problems.

At this same meeting, the Board met with Bertram Brown, Director of the National Institute of Mental Health, to discuss the current changes in NIMH organization and funding and their implications for psychology. The Board also heard from the Executive Officer on the importance of work at the state and local levels in connection with federal revenue-sharing programs, both general and special, and that Central Office staff was working with state and local associations to ensure that funds potentially intended for psychological training and services not be dissipated.

B. The following resolution was voted by Council at its Special Meeting on March 31–April 1, 1973:

The Council of Representatives of the American Psychological Association, in special meeting called "to consider the phaseout and termination of federal support of training, research, and service," notes with deep concern and dismay the human consequences of present budget policies. As representatives of a science and profession dedicated to human welfare, we call upon the members of our Association to urge the administration and the Congress to reassert human priorities. We are especially concerned because the emerging patterns of federal revenue sharing involve a radical reduction in our national investment in human welfare.

C. Council also voted at its Special Meeting that Central Office and the Board of Directors be given a vote of confidence and thanks for their efforts in the attempt to remedy the effects of the funding cuts.

D. At its November 1973 meeting, the Board heard an informal report of activity by the Scientific Affairs department and other segments of Central Office with respect to proposed HEW regulations and possible Congressional action concerning research with human subjects. It was the consensus of the Board that regulations were much to be preferred over legislation, and encouraged Central Office to continue its monitoring efforts.

E. By mail ballot September 14, 1973, the Board voted to have the Association join the National Association for Mental Health (NAMH) in a suit to release

impounded training and research funds. It was the Board's judgment that the action was in keeping with the sentiments expressed by Council at its Special Meeting, and that the release of the funds for support of training of mental health personnel and for mental health research would be in the public interest as well as in the interests of APA members. The basis of the suit was reviewed and approved by APA's attorneys in consultation with the NAMH counsel.

F. Council was informed at its January 1974 meeting that the Standards for Educational and Psychological Tests had been approved for publication (early in 1974) by the three participating organizations: American Education Research Association, National Council on Measurement in Education, and the American Psychological Association (approved by the Board of Directors in November 1973).

G. Upon recommendation of the Committee on Scientific Awards and the BSA, the Board of Directors at its November 1973 meeting voted an additional \$500 (over the \$1,000 approved earlier) for the Early Career Awards, so that each of three recipients could receive a citation and \$500. The Board was informed that the Committee plans to make three awards each year, from the following areas: Year 1, human learning/cognitive, psychopathology, physiological; Year 2, animal, personality, developmental; Year 3, methodological, social, sensation/perception.

H. Council was informed that a Task Force on Health Research has been formed under the aegis of BSA's Ad hoc Committee on Newly Emerging Areas of Research (NEAR), with the following objectives: compile and disseminate information on psychological research in health; facilitate communication among researchers; survey resources for expansion and stimulation of health-related research (survey interest and resources, define potential roles for psychologists, identify challenges); identify research problem areas; encourage training innovations; and establish liaison between the American Psychological Association and other appropriate groups in health research.

I. Council was informed that a Task Force on Human–Environment Relations has been formed under the aegis of the NEAR committee of BSA, with the following objectives: stimulating psychological research in the area of human–environment relations; providing information about alternative educational models and courses of instruction in human–environment relations; stimulating an understanding of the potential application of research knowledge in the human–environment field to public policy issues; and developing interdisciplinary contacts.

J. The following reports were received:

1. Annual Report of the Board of Scientific Affairs and reports from the following committees, representatives, and task forces reporting to the Board:

- a. Committee on Precautions and Standards in Animal Experimentation.
- b. Committee on Scientific Awards.
- c. Committee on Psychological Tests and Assessment.
- d. Ad hoc Committee on Psychology, Family Planning, and Population Policy.
- e. Task Force on Health Research.
- f. APA Representative to AAAS.
- g. APA Delegation to the Inter-Society Color Council.
- h. APA Representative to the National Society for Medical Research.
- i. APA Representative to the Social Science Research Council.

XII. EXTERNAL AFFAIRS

A. At its February 1973 meeting, the Board received a communication from the Policy and Planning (P&P) Board, suggesting that clarification was needed in the stand the Board of Directors had taken on the principles laid down by the 1969 Ad hoc Committee on Public Affairs (*American Psychologist*, 1969, 24, 1-4). The Board agreed with the P&P Board.

The Board feels that the ordering of scientific concerns, professional concerns, and social problems on a dimension of centrality to the purposes of APA is reasonable, in the sense that the Association's mandate to take public positions becomes less clear and broad as one moves from policies that affect psychology as a science, through policies that affect professional practice in specific settings, to general social policies. The Board does not feel, however, that this ordering should necessarily determine priorities for action or the level of involvement represented by actions, as proposed in the 1969 report. That report did not concern itself with the question of the *obligation* of psychology and psychologists to take action on public issues involving the effects of psychological work on individuals, groups, or society as a whole, a matter discussed by the Board in May 1972. For example, where psychological tools or findings are used inappropriately or in a way that exacerbates a social problem, or conversely, where psychological tools or findings could potentially contribute to the solution of a social problem, a high level of priority and action involvement may well be indicated. Furthermore, the Board also recognizes that the distinction between scientific, professional, and social concerns is often difficult to draw. It may be particularly misleading in view of recent emphases on scientific research applied to social problems and on the conduct of research in professional or action contexts.

B. At its November 1973 meeting, the Board authorized the Executive Officer to seek external funding for a 1974 Public Policy Conference.

C. At its February 1973 meeting, the Board was informed that an additional \$1,500 had been received from the Asia Foundation for use in paying Foreign Affiliate fees and journal subscriptions of Asian psychologists.

D. At its June 1973 meeting, the Board referred to the Editor of the *American Psychologist* a recommendation from the Committee on International Relations in Psychology that a special issue of the *AP* be devoted to overviews of psychology in countries other than the United States and Canada. The Editor indicated that he would consult with the Committee for suggestions on a special editor to be named for the issue. The Committee also reported its support for the membership of APA on the International Council of Scientific Unions-Abstracting Board.

E. At its January 1974 meeting, Council received an information item from the Committee on International Relations in Psychology with respect to procedures for requesting action by the International Union of Psychological Sciences. (See Item III-G, these Proceedings.)

F. The Executive Committee reported to the Board at the February 1973 meeting that it had referred to the Editorial Board of the *APA Monitor* a recommendation from the Policy and Planning Board that there be a student section of the *Monitor* and that the *Monitor* be distributed in bulk to graduate departments.

G. At its meeting in August 1973, Council heard a motion calling for mandated space in the *APA Monitor* for segments of the governing structure, with a committee of Council to receive the material and monitor the activity. The motion was referred to the Board of Directors, which discussed the matter at its meeting in November 1973. Under present concepts, the *Monitor* is a nonarchival publication which avoids competition with the *American Psychologist* by journalistic reporting of "news" that may affect the membership, rather than publishing mandated articles from the APA governing structure. It attempts to maintain its credibility by reporting pro and con positions in the development of possible policies under consideration by all parts of the APA structure. The Board encourages Council and all boards and committees to be critical of the *APA Monitor* and its staff in the selection, impartiality, and comprehensiveness of its news stories. The Board recommended, therefore, that Council defeat the motion for mandated space and the establishment of a Council committee to receive material for space and to oversee its publication. A substitute motion, offered by the Psychologists for Social Action through Hannah Levin, Council Representative from Division 27 (Community), was introduced at the January 1974 meeting of Council, calling for mandated space in the

Monitor for any APA committee or "to diverse groups on an impartial basis, and a Council committee of three to handle all grievances relating to the publication practices of the *APA Monitor*." The first part of the motion was withdrawn, and Council voted to defer until its New Orleans meetings action on the proposed Council committee.

H. By mail ballot Council approved the affiliation of APA with the American Council of Learned Societies, with Rule of Council 10-5.2 to be amended accordingly.

I. At its meeting in February 1973, the Board was informed that the Central Office historical display project had received a contribution of \$50 from Division 1 (General) and "up to \$100" from Division 26 (History). So far, there have been displays on E. G. Boring, E. B. Titchener, R. M. Yerkes, and timing devices.

J. At its January 1974 meeting, Council received the Final Report of the Ad hoc Committee on Legislative Affairs and took the following actions with respect to the report, recommendations from the Board of Directors, and motions introduced by Council members:

1. Defeated a recommendation that an Office of Legislative Affairs be established in the Central Office;

2. Approved continuing liaison with governmental officials on the utilization of clinical psychologists in Medicare and Medicaid, the Executive Officer instructed to call upon appropriate consultants as needed;

3. Defeated a recommendation calling for a study as to the feasibility and cost of an in-house attorney for APA, on the grounds that investigations already undertaken by Central Office and the Board of Professional Affairs have indicated that the legal needs of APA are so diverse that the total costs of an in-house attorney plus outside consultation would be substantially greater than the present arrangement;

4. Concurred with the recommendation that the composition and function of the continuing Committee on Legislative Affairs (see below) be reviewed at the end of that committee's first year;

5. Concurred with the decision of the Executive Officer that the Legislative Affairs Officer be assigned to the office of the Director of Programs and Planning;

6. Amended Rule of Council 10-9.1 establishing the Committee on Legislative Affairs (COLA), adopted by Council at its August 1973 meetings, to substitute a member of the Policy and Planning Board for the Chairman of the Committee on State Legislation as a mandated member of COLA, and to add the Chairman of the Committee on Psychological Tests and Assessment as a mandated member, thus increasing the size of the continuing committee from nine to ten members. The new Rule of Council reads as follows:

There shall be a Committee on Legislative Affairs reporting to Council through the Board of Directors. The Committee is responsible for recommending the initiation and modification of governing units dealing with critical legal,

statutory, and budgetary practices and proposals which are pertinent to the support of and utilization of psychology by the public, and for recommending the most effective structural and procedural arrangements to accomplish these ends. Specifically, the Committee will recommend legislative policy; determine current and future legislative, regulatory, and budgetary targets of probable attainability; recommend priorities for action; provide consultation to staff, boards, and committees as to goals, strategies, and existing deficiencies in the legislative or regulatory area; and recommend appropriate liaison by APA when needed with other professional and scientific groups with whom we share common legislative interests.

The Committee shall consist of ten members: the Chairman of the Committee on Health Insurance, a member of the Policy and Planning Board, a member of the Board of Professional Affairs, a member of the Board of Scientific Affairs, a member of the Education and Training Board, a member of the Board of Social and Ethical Responsibility for Psychology, the Chairman of the Committee on Psychological Tests and Assessment, and three elected members who shall be members of the Council of Representatives at the time of their election. The term of office of elected members shall be for three years so staggered that at least one member is elected each year. In making nominations the Committee on Nominations and Elections of Council shall attempt to ensure that candidates possess nationally recognized expertise in legislative or administrative affairs in the area of the educational, professional, or scientific contributions of psychologists to human welfare.

K. Summaries of the discussions and actions leading to the establishment of a continuing Committee on Legislative Affairs appear in the Minutes of Council in December 1972, March 1973, and August 1973, together with the Minutes of the Board of Directors meetings of February 1973, May 1973, June 1973, August 1973, November 1973, and January 1974.

L. At the Special Meeting of Council in March 1973, a motion was received directing that the APA join, as participant, the class-action suit proposed by the Council for Advancement of the Psychological Professions and Sciences (CAPPS) against Blue Cross/Blue Shield under the Federal Employees Benefit Plan, for failure to permit freedom of choice for the delivery of psychological services. The issue was referred to the Board of Directors, with a request for a report back to Council within 60 days, the sense of Council at that meeting being that APA should become involved, unless the Board saw possible dangers to the Association.

Also at the Special Meeting, Council voted that the President of APA appoint an ad hoc committee to examine the issues, interactions, and relationships between the APA and CAPPS, and to propose, recommend, and specify the relationships, and the terms and provisions of any relationships, which will continue after September 1973, to the Board of Directors and Council. An interim report from the Ad hoc Committee on APA-CAPPS Relationships was received by Board and Council in August 1973, and a Final Report in January 1974.

Discussions by the Board of Directors at its meetings in May, June, and August of 1973, as reported in

the Minutes of these meetings and to Council, resulted in a recommendation that APA not participate in the CAPPS suit against Blue Cross/Blue Shield, and at the Council meeting in August 1973 action on a resolution that APA participate was tabled, by vote of Council.

M. At its meeting in January 1974, Council received the Final Report of the Ad hoc Committee on APA-CAPPS Relationships, recommendations from the Board of Directors with respect to the report, motions from Council members, together with material distributed to Council members at the meeting by CAPPS. Council heard statements by Wilse B. Webb, Chairman of the APA-CAPPS committee, and Norman Garnezy, a member of the committee. In addition, Council received a report from the Policy and Planning Board presenting a series of recommendations and proposed Articles of Incorporation and Bylaws for the new advocacy organization recommended by the Ad hoc Committee and the Board of Directors. The sequence of actions voted was as follows:

1. Approval of the Board of Directors recommendation that the APA does not accept CAPPS as an advocacy organization which will meet appropriately the needs of all psychologists.

2. Referral to the Policy and Planning Board, for study and recommendations, the following actions proposed by the Ad hoc Committee: (a) guidelines for a legally independent advocacy organization, (b) actions to be taken to establish an advocacy organization structured upon the guidelines, and (c) support to be provided by APA of the proposed advocacy organization.

3. John Stern, Chairman of the Policy and Planning (P&P) Board, immediately introduced the P&P report, summarized its provisions, and moved that Council take action on the eight P&P recommendations. After extended discussion, Council voted to approve all eight, as follows:

- a. That the draft Bylaws and Articles of Incorporation for an Association of American Psychologists (AAP; *Secretary's note*: name changed later to Association for the Advancement of Psychology) be approved in principle by the Council subject to review and minor modification by the initial Board of Trustees of that organization;

- b. That the Board of Directors be requested to appoint an initial 15-person Board of Trustees of the AAP from the list of APA members provided by P&P, the Board of Directors, and accepted nominations from Council;

- c. That the initial Board of Trustees of AAP be requested to file articles of incorporation for AAP;

- d. That the initial Board of Trustees be requested to convene in early February 1974 to (1) arrange for the election of an additional nine trustees and establish staggered terms of office by lot for all trustees, (2) set priorities for programmatic efforts, (3) employ

- an Executive Director, and (4) otherwise attend to initial organizational and administrative problems;

- e. That a loan of APA funds to AAP be authorized for expenses incurred in Steps b, c, and d, and for conduct of a membership and dues pledge drive among APA members and affiliated psychological associations, such drive to be done at cost;

- f. That it be specified in the note of agreement that repayment of the loan will be made from funds collected in Step e above;

- g. That the Treasurer of APA be authorized to develop a contract with AAP for provision of business and administrative services, including collection of dues by APA;

- h. That a Rule of Council be passed forbidding common membership on the APA Board of Directors and the AAP Board of Trustees, or any like advocacy organization for psychologists with a 501(c)-6 IRS tax-exempt classification.

In connection with h above, the Rule of Council is to be written in such a way that officers of affiliated state associations with a 501(c)-6 status may be elected to the APA Board of Directors or the AAP Board of Trustees.

4. The Ad hoc Committee on APA-CAPPS Relationships was discharged with thanks.

5. Under a voted suspension of the rules, Council received a statement from CAPPS calling for an APA statement in support of CAPPS activity with respect to the suit against Blue Cross/Blue Shield. Council voted that the exact wording of such a statement be left to the Board of Directors, with circulation to Council as soon as possible. The vote was unanimous, and expressed Council sentiment that the language should be in legal form, to protect the legal action by CAPPS, as well as the position of the APA.

N. The following reports were received:

1. Annual Report of the Committee on International Relations in Psychology.

2. Annual Report from the APA Representative to the International Union of Psychological Science.

3. Interim and Final Reports of the Ad hoc Committee on Legislative Affairs.

4. Interim and Final Reports of the Ad hoc Committee on APA-CAPPS Relationships.

5. Final Report of the Ad hoc Committee on P.L. 92-157 and P.L. 92-603.

XIII. CENTRAL OFFICE

A. The following actions were taken during the year in the area of employee benefits:

1. In consideration of the fact that all former Central Office participants in the APA Retirement Plan with John Hancock elected to transfer their funds to TIAA/CREF, and further noting that all funds had been

transferred, the Board voted at its February 1973 meeting to dissolve the APA Retirement Plan Trust and authorized the Executive Officer to notify Meredith P. Crawford, Charles S. Gersoni, and Boris E. Cherney that they were relieved as Trustees and that their services in that capacity were appreciated. At its August 1973 meeting, the Board voted to authorize the Executive Officer to investigate, evaluate, and if appropriate, implement the TIAA/CREF Supplemental Retirement Annuity Plan as an optional feature for staff personnel with the understanding that, if implemented, the option will not entail any cost to APA. At its meeting in January 1974, the Board received a recommendation that the President of the APA convey the Association's concerns about the group health plan offered by TIAA/CREF, a plan which recognizes the services of psychologists only under medical referral, voting to instruct the Executive Officer to implement this suggestion.

2. At its meeting in February 1973, the Board voted that the APA Pay Table for graded employees be revised in two steps to grant pay raises comparable to the federal pay raise with a 3% increase July 1, 1973, and 2.14% January 1, 1974. At its November 1973 meeting, the Board received information about the new federal pay scale, implemented in October 1973, voting to continue the present pay scale for graded personnel in Central Office for 1974 but to adopt a revised scale for 1975.

3. At its May 1973 meeting, the Board considered the appropriateness of its methods for handling grievances in the Central Office. The consensus was that if a hearing committee were required to arbitrate a grievance it would be preferable that it not be made up of members of the Board of Directors.

4. At its November 1973 meeting, the Board received copies of the APA Central Office Affirmative Action Program and a memorandum concerning the Program from the Board of Social and Ethical Responsibility for Psychology (BSERP). The Board of Directors voted its unanimous approval of the Program. The Board noted BSERP's concerns with sympathy, but with respect to specific recommendations, the Board regarded the Program as genuinely responsive to legal and ethical requirements, and reluctantly decided that recommended further activity in special staffing and research is not financially feasible. The Board took note of BSERP's specific suggestions to the Executive Officer concerning proposed goals and objectives for the Program, and observed that the recommended restriction of recruiting for specific positions to minority applicants is contrary to legal requirements and to the spirit of affirmative action in the context of equal opportunity. The Board suggested, with respect to the BSERP recommendation, "that APA initiate, develop, and support programs for the training of psychologists as affirmative action experts," that BSERP consider sponsoring a workshop at the annual convention for

psychologists involved in such programs. The Board agreed that research relevant to affirmative action programs should be disseminated, and the Board encouraged BSERP to devote a part of its resources to this purpose. Copies of the Plan are to be widely distributed when it has been officially accepted by the Office of Federal Contract Compliance.

B. The following actions were taken at the January 1974 meeting of Council in the area of Central Office organization:

1. Deferred until the New Orleans meeting a motion to establish a management study task force to study the Central Office and its relation to the APA governing structure, asking Central Office to gather information on possible costs of such a study. The Board of Directors also indicated its plans to study this matter at its May 1974 meeting.

2. Received a motion asking for more information about Central Office pay scales, conditions of employment, etc., and was informed that the information is available in the Central Office Organization and Procedures Manual, copies of which were provided at the meeting.

3. Was informed that the Board of Directors concurred in a motion asking that staff study current operations in Central Office that might be moved to a more outlying location effectively and with net savings, with a report to Council at the New Orleans meetings.

C. Central Office staff developed a new system for the handling of annual reports from boards and committees. Action items from such reports were excerpted for consideration by the Board of Directors and the Council of Representatives, but the reports themselves were assembled in a separate book, also distributed to Council members but not a part of the agenda books, as in the past.

D. The Executive Officer reported the following appointments and terminations of senior staff personnel during 1973: *appointments*, Arthur Centor, Administrative Officer, Professional Affairs; *terminations*, Tena Cummings, Assistant Director, Administrations and Operations; William Learmonth, Associate Director, Psychological Abstracts Development System; Henry Salmon, Manager, Publications Business Services; Richard Caputo, Manager, PAIS Educational Services; Judith Cates, Administrative Associate, Policy Studies; Robert Gorman, Systems Analyst; Frank Whiting, Project Director, Standards for Psychological Service Facilities; Estelle Mallinoff, Editor, Separates; and Gottlieb Simon, Associate Administrative Officer, Professional Affairs.

XIV. FINANCIAL AFFAIRS

A. The Finance Committee, and both the Board of Directors and the Council of Representatives, paid

considerable attention during the year to the need for maintaining appropriate controls over the financial ramifications of decisions made and adopted by various segments of the Association. These discussions led to the following actions, voted by the Council at its August 1973 meeting:

1. A new Rule of Council, 150-1.7, to read as follows:

Any action taken by the Board of Directors during an operating year which would increase the originally budgeted expenses by \$2,500 or more in that year will be reported to Council members in writing within thirty days after the action(s) authorized. This notification will include an explanation of the reasons for the action(s) and the manner by which these additional expenses will be financed, e.g., by increased prices for existing products and/or services, sales of new products and/or services, reductions in other activities, or absorbed from surplus.

2. To amend Rule of Council 20-4.1 by the addition of the following sentence:

Any matter involving an expenditure of \$15,000 or more shall not be adopted on the day of the Council meeting at which it is introduced but shall be referred to the Finance Committee for evaluation and recommendation in terms of financial feasibility, and the Finance Committee shall report its findings to the Council on the next day that Council meets at which time Council will take formal action

B. The importance of long-range financial planning was also emphasized, and the following action was voted by Council at its January 1974 meeting, upon recommendation of the Finance Committee and the Board of Directors: to establish as the overall Association financial goal for the period 1974-1978 the accumulation of a \$1 million liquid reserve by the end of 1978, a reserve that would represent about the equivalent of one month's operating expenses in 1978, where the "liquid reserve" constitutes the Association's equity, exclusive of equity in nonliquid assets (land, building, furniture, and equipment) and, to achieve the goal, that subgoals be assigned to the major programs as follows:

PROGRAM	FIVE-YEAR GOALS (1974-1978)
Services and Activities	Gross contribution [†] amounting to 20% of direct expenses
Publications and Communications	Gross contribution [†] amounting to 20% of direct expenses
All Other (mainly investments)	\$500,000 surplus
General Administrative Expense	Shall not exceed approximately 15% of the total direct expenses of the Services and Activities and Publications and Communications programs

To ensure that plans are developed to achieve these goals, Council directed the Board of Directors to as-

sign responsibility to boards and committees and/or the Executive Officer, as appropriate, to develop plans for the period 1974-1978 such plans to be reported to Council by September 1974.

C. The following changes were voted in the 1973 Budget:

1. By the Board of Directors at its February 1973 meeting, an increase of \$33,500 in estimated expenses for membership in the American Council of Learned Societies, membership in the Accreditation Council for Facilities for the Mentally Retarded, for increased expense allowance to the Board of Professional Affairs and increases reflected in a new Pay Table for graded employees in Central Office.

2. By Council at its Special Meeting in March 1973, an increase of \$59,000 in estimated expenses for a new Student Aid Committee, an additional staff member in the legislative affairs area, a new Committee on Legislative Affairs, mailing tapes to state associations, reimbursement of travel expenses for the Special Meeting, and an Ad hoc Committee on APA-CAPPS Relationships.

3. These changes, as of April 1, 1973, resulted in estimated budgeted revenues of \$6,358,800, estimated budgeted expenses of \$6,324,400, with a net of revenues over expenses of \$34,400.

D. The Executive Officer alerted Council, at its meeting in March 1973, to its obligations in view of the financial crisis facing the Association: 1971 and 1972 were deficit years; 1973 showed a strong possibility of being a deficit year; and an even more serious deficit situation was indicated for 1974, on the basis of early budget planning. Council members were urged to submit their suggestions for meeting this crisis to the Finance Committee and to be prepared for serious consideration of the Preliminary 1974 Budget at the Montreal meetings in August 1973.

There was extended discussion of the Preliminary Budget at Montreal, with general agreement that a key problem is how to develop a system for setting priorities, in view of the limited funds available. Straw votes were taken—essentially negative toward any increase in dues greater than \$5, toward special assessments toward increasing membership by lowering requirements for Member status; essentially positive toward devising a system for Council members to indicate priorities, and to try to increase sales of present and new products and/or services.

The Board of Directors took a number of actions at its November 1973 meeting intended to turn the anticipated deficit in the 1974 Budget into a surplus, including a major reduction in the budgets for boards and committees.

At the January 1974 meeting of Council, the 1974 Budget was adopted, amended to restore the amounts available to boards and committees to the levels spent in 1973, or to 1974 requests, whichever is lower, and

[†] Excess of revenues over direct expenses.

with a reduction in anticipated income of around \$15,000, due to the decision to delete the Convention Registration Fees for students. As amended, the 1974 Budget anticipates revenues of \$6,164,000, expenses of \$6,126,000, and a budgeted excess of revenues over expenses of \$38,000.

At the January 1974 meeting, there were two sessions of discussion of the 1974 Budget as a Committee of the Whole. Discussion in the first session emphasized the proposed cuts in board and committee budgets, as well as the way in which the budget for Publications and Communications was presented. In connection with the latter, Council accepted a motion to divorce, in future budget presentations, the allocation of General Administrative Expenses and Transferred Office Expenses from net income and/or deficit figures on a formula basis. The purpose of the motion was to adopt a system of "Direct Costing" as the basis for accounting and budgeting to make clearer the revenue, direct expenses, and, hence, the gross contributions of the several journals and activities of the various programs—particularly "Services and Activities" and "Communications," thereby eliminating arbitrary allocations from the expenses of the programs. Implementation of this was left to the Finance Committee. (The program goals indicated in Item XIV-B of these Proceedings were developed in accordance with the "Direct Costing" motion.)

In the second discussion in Committee as a Whole, a number of suggestions were made of ways to increase income or cut expenses. The Treasurer, in his capacity as Chairman of the Finance Committee, reported that a dues increase as of 1975 could be anticipated, and that the Committee will be considering the level of such a dues increase, also taking into account the various suggestions of Council. Straw votes were taken on a number of them, as follows: essentially against the elimination or reduction of division dues allocations, special assessments for 1974, dues set according to income level, encouragement of members to make APA a beneficiary under life insurance plans; essentially for voluntary contributions solicited from members for specific functions, going to a per diem approach for APA travel (but see below); about even on the idea of an automatic increase in dues tied to a relevant government index.

After rising from the Committee as a Whole, and with further information about various problems connected with adopting a per diem plan for APA travel, Council voted to table the motion, with a request to Central Office to continue ways of reducing travel expense, not only of boards and committees but also of staff.

E. At its Special Meeting in March 1973, Council voted to establish an Ad hoc Committee on Student Aid (COSA), to be appointed by the President and composed of six members of Council knowledgeable

about the financial aid needs of students, the Committee to be charged with developing plans for a suitable APA-administered doctoral student aid program (loans and/or scholarships), to which any graduate student in a state approved or regionally accredited doctoral program in psychology shall have the right to apply for aid. In addition to the six Council members, the President, Executive Officer, Treasurer, and Business Manager of the Association shall be ex officio members of COSA without vote. The Committee was to report its final plans to Council no later than the Montreal meetings and was given a budget of up to \$10,000 in 1973. The Committee submitted a progress report in June 1973, and Council, at its August 1973 meeting, voted to authorize COSA to negotiate with the United Student Aid Fund and an insurance company or companies, with a view toward establishing a loan program for doctoral candidates in psychology. Referred to the Finance Committee was a COSA recommendation that a \$10 increase in dues be authorized, or a special assessment, effective in 1975, if the above negotiations are successful, to be continued for a period not to exceed three years. At its meeting in January 1974, Council received the final report of the Ad hoc Committee, concurring in the Board of Directors recommendation that the committee be discharged with thanks and the Director of Business Affairs charged to pursue the matter of a Student Loan Fund.

F. At its meeting in November 1973 the Board considered the desirability and feasibility of allowing members to allocate dues as a means of establishing priorities (a motion on this had been tabled at the Council's Special Meeting, and a similar motion had been introduced at the August 1973 meeting). The Board voted to recommend to Council that allocation of dues not be adopted at this time and asked staff to develop a proposal for a method of inquiring from members as to their programs' areas of prime interest to permit Council to consider these expressions of member interest in arriving at priorities in future budgets. Staff recommended to the Board in January 1974 that the Policy and Planning Board be asked to develop a method of polling members on these issues.

At its meeting in January 1974 Council voted that allocation of member dues (to indicate priorities) not be undertaken at this time, having been informed also that the Finance Committee is planning to develop a procedure for getting priority judgments from Council members, and that the Policy and Planning Board is continuing its planning for a system of soliciting priority judgments from the membership.

G. The Board of Directors, upon recommendation of the Finance Committee, approved the appointment of Ernst and Ernst to conduct the 1973 Audit.

H. The Board of Directors voted to accept the following grants:

1. A continuation grant from the Department of

Health, Education, and Welfare (HEW) for \$39,645 to support the project "Psychology Graduate Training Standards and Evaluation," for the period July 1, 1973, to June 30, 1974.

2. A continuation grant from HEW for \$72,216 in support of the project "Standards for Psychological Service Facilities," for the period May 1, 1973, to April 30, 1974.

3. A continuation grant from HEW for \$11,880 in support of the project "Visiting Psychologists to Field Services" for the period July 1, 1973, to June 30, 1974.

4. A continuation grant from HEW for \$89,000 to support the project "Conference on Professional Training in Psychology," for the period July 1, 1973, to June 30, 1974.

5. A grant from HEW for \$150,000 to support the project "Headstart Program," for the period June 30, 1973, to June 29, 1974.

I. At its February 1973 meeting, the Board was informed that as of January 10, 1973, the total of \$54,000 approved as a loan according to an agreement dated July 23, 1970, between APA and the Black Students Psychological Association (BSPA) had been advanced. Board members expressed the hope that by the termination date, June 30, 1973, a report of BSPA's activities during the three years would be available. As reported in Item IX-C of these Proceedings, the Board voted at its November 1973 meeting that BSPA need not repay the loan.

J. At its May 1973 meeting, the Board of Directors voted to add three Council members to the Finance Committee, on an ad hoc basis for 1973, so that Council would have a larger reservoir of expertise and understanding of APA's financial problems. The three added were David G. McDonald, Samuel H. Osipow, and Robert Perloff. A Rule of Council is to be developed to increase the size of the Committee from four to seven on a continuing basis.

K. At its November 1973 meeting, the Board voted to extend signature authority to the Controller and to rescind previous authority extended to the Manager, Financial and Computer Services Department, by passing the following resolution:

Resolved, that the American Security and Trust Company, Washington, D.C., is hereby continued as a depository for the funds of this Corporation, and is hereby authorized and directed to pay checks and other orders for the payment of money when signed by any one of the following:

Executive Officer	Unlimited
Treasurer	Unlimited
Director of Business Affairs	Unlimited
Controller	Up to \$500 on the general account and unlimited on the payroll account.

L. The following reports and minutes were received:

1. The Minutes of its meeting on July 12-13, 1973,

were submitted as the Annual Report of the Finance Committee.

2. Interim and Final Reports from the Ad hoc Committee on Student Aid.

3. Final Report of the Ad hoc Committee on APA Dues Structure.

XV. COMMUNICATIONS FROM OUTSIDE ORGANIZATIONS

A. At its February 1973 meeting, the Board of Directors received a request from the American Psychological Foundation (APF) that APA give consideration to increasing the size of its contribution to APF of gross revenues from APA-owned copyright material, now at 20%, to 50%. The Board voted to refer the matter to the Publications and Communication (P&C) Board for a recommendation, and, upon recommendation of the P&C Board, voted at its November 1973 meeting to increase the APF's share of copyright permissions revenues to 40% of the gross (equivalent to a 50-50 split between APA and APF after expenses) to be implemented with calendar year 1975.

B. At its June 1973 meeting, the Board was informed that the APF had been named as the residuary legatee in the will of Esther Katz Rosen, a dues-exempt Fellow of APA who died on April 13, 1973.

C. At its November 1973 meeting, the Board received with thanks a report from the Insurance Trust and also heard from the President of the Trust, taking the following actions with respect to the Trust's recommendations:

1. Voted to amend the Agreement and Declaration of Trust, Article IV, Section 6, as follows:

Section 6. [SEGREGATION OF ASSETS.] *FUND ACCOUNTING.* In the event the Insurance Trustees shall negotiate or otherwise obtain more than one policy of insurance, separate accounting funds shall be maintained by such Trustees for each policy [and all monies pertaining thereto shall remain segregated and the investments of such monies shall likewise be segregated by the Investment Trustee] in order that the assets, liabilities, and equity of each principal policy fund can be separately identified and through which retrospective adjustments and premium refunds attributable to each insurance policy can be recorded. Notwithstanding any provision to the contrary contained herein, no premium payments or refunds shall be permitted to be made by the Insurance Trustees other than in connection with the specific policy for which said monies are directly attributable. This limitation shall not be construed as restricting the Insurance Trustees from using income derived from the Fund for the purpose of developing new insurance programs. In no event will any income of the Fund be distributed to any participant at any time and if upon termination of the Trust there remains any accumulation of income the same shall be distributed to the American Psychological Association. In order to segregate the income derived from each principal policy, a separate

"Income Fund" shall be established into which income derived from dividends and capital gains (and losses) realized by the several principal policy funds shall be credited (or charged) and out of which the expenses of the Insurance Trust will be paid.

2. Voted to elect Gardner Lindzey and Joseph Weitz as new members of the Trust, expressing gratitude to those serving previously on the Trust and with special thanks to Benjamin Shimberg for his long-time dedication and valuable contributions.

3. Heard with interest of the Trust's plans to offer newly elected members (as of 1974) a free \$10,000 life insurance policy for a stated period.

D. At its January 1974 meeting, the Board considered a communication from the Association of Gay Psychologists (AGP), including a list of the objectives of that Association as adopted at its Montreal meeting and a list of eight demands it wished APA to implement and publicize. The demands, and the actions voted by the Board, are as follows:

1. "A National Task Force on Homosexuals as Persons shall be appointed by the President of the American Psychological Association in consultation with the AGP with at least 50% of the Task Force being members of the AGP." Referred to the Board of Social and Ethical Responsibility for Psychology.

2. "APA shall advocate the removal of the listing of 'Homosexuality' from the Diagnostic and Statistical Manual II of the American Psychiatric Association." The Board noted that the latter association has already done this.

3. "All panels on homosexuality (at national and regional meetings) shall include at least one member of the AGP as a panel member, and all paper sessions (at national and regional meetings) shall include at least one member of the AGP to serve as discussant." The Board noted that divisions are responsible for developing their programs, and that it would be inappropriate to interfere with their prerogatives. The AGP would need to deal directly with the divisions (and the regional associations) if it wishes to pursue this matter.

4. "APA shall support the elimination of parents' sexual orientation as a factor in decisions relating to parents' rights to rear their own children." The Board felt this demand was outside APA's purview.

5. "APA shall advocate the repeal of all legislation restricting sexual relations between consenting adults." The Board felt this also was outside APA's purview.

6. "APA shall take affirmative action in the elimination of discrimination on the basis of sexual orientation in APA's Central Office and with all companies with which APA does business, and support adding sexual orientation clauses to antidiscrimination laws." The Board noted that to inquire about a person's sexual orientation would be illegal, probably, and in any case quite inappropriate.

7. "APA shall establish a Central Office personnel person to handle all APA members' and associates' charges of discrimination on the basis of sexual orientation." The Board noted that such charges should be filed with the Committee on Academic Freedom and Conditions of Employment, and that the machinery for handling such charges exists.

8. "APA shall include members of the AGP in the Visiting Psychologist Program." Selecting participants in this program is done on the basis of potential contribution; membership in any given association would not be a relevant criterion.

The President, Albert Bandura, agreed to report the Board's actions to AGP.

E. At its February 1973 meeting, the Board noted with concern a misstatement of fact concerning election of Council members to the Board of Directors, appearing in an advertisement in the February 1973 *APA Monitor*, calling for participation in a new organization to be called "Psychologists for a Representative and Responsible APA." The ad stated that the Board of Directors acts as a nominations and elections committee for the election of Council members to the Board, whereas Council itself nominates via a nominating ballot sent to each Council member, followed by an election ballot that asks each Council member to rank order the nominees who have received the most nominations on the previous ballot. The Board asked that the Recording Secretary write a letter to the Committee sponsoring the ad, asking that they publish a retraction, and that the letter be published in the *Monitor* in the form of a letter to the Editor.

F. See Item XII-L for actions with respect to the Council for the Advancement of the Psychological Professions and Sciences (CAPPS).

Officers, Boards, Committees, and Representatives of the American Psychological Association: 1974

APA OFFICERS

President: Albert Bandura (1974)¹
Stanford University
President-elect: Donald T. Campbell (1974)
Northwestern University
Past President: Leona E. Tyler (1974)
University of Oregon
Recording Secretary: John J. Conger (1974-76)
University of Colorado
Treasurer: Robert Perloff (1974-77)
University of Pittsburgh
Executive Officer: Kenneth B. Little (1968-77)
APA Central Office

BOARD OF DIRECTORS

The President, the President-elect, the Past President, the Recording Secretary, the Treasurer, the Executive Officer, and:

Herbert C. Kelman (1972-74)
Leonard Krasner (1973-74)
Richard C. Atkinson (1973-75)
M. Brewster Smith (1973-75)
John I. Lacey (1974-76)
Rogers Wright (1974-76)

COUNCIL OF REPRESENTATIVES

The Council of Representatives is composed of the Board of Directors, Division Representatives, and State Association Representatives. The Representatives for the current year, with term of office, follow:

Norman Abeles (1973-75)—Michigan
George W. Albee (1973-75)—Div. 12
Richard C. Atkinson (1973-75)—Board of Directors
Albert Bandura (1974)—President
Allan G. Barclay (1972-74)—Div. 12
Morton Bard (1974-76)—Div. 27
Jules Barron (1974-75)—Div. 29

H. T. Bassett (1973-75)—Wisconsin
Josephine P. Beebe (1973-75)—Connecticut
Ernst G. Beier (1972-74)—Utah/Wyoming/Montana/
New Mexico
Gershon Berkson (1974-76)—Div. 33
Sidney W. Bijou (1972-74)—Div. 12
Theodore H. Blau (1973-75)—Div. 12
Lyle E. Bourne, Jr. (1972-74)—Div. 3
Donald T. Campbell (1974)—President-elect
Irvin L. Child (1974-76)—Div. 10
Richard K. Clampitt (1974-76)—Minnesota
John J. Conger (1974-76)—Recording Secretary
Jonathan W. Cummings (1973-75)—District of
Columbia
Nicholas A. Cummings (1973-75)—California
Mary Ellen Curtin (1972-74)—Kentucky/Tennessee
Robert C. Davis (1972-74)—Div. 26
Gordon F. Derner (1974-76)—Div. 12
Martin Deutsch (1972-74)—Div. 9
James A. Dinsmoor (1972-74)—Div. 25
Francis J. DiVesta (1972-74)—Div. 16
Herbert Dörken (1974-76)—California
Jan D. Duker (1973-74)—Div. 16
Frank W. Finger (1973-75)—Div. 3
Jo-Ann E. Gardner (1974-76)—Div. 9
Sol L. Garfield (1973-75)—Div. 12
Marcia Guttentag (1974-76)—Div. 8
Elizabeth P. Hagen (1973-75)—Div. 5
Leon P. Hall (1973-75)—Div. 16
Florence C. Halpern (1973-75)—Div. 12
Carmi Harari (1974)—Div. 32
Robert S. Harper (1972-74)—Div. 2
Harry Helson (1974-76)—Div. 1
Joseph S. Herrington (1972-74)—Pennsylvania
Lloyd G. Humphreys (1973-75)—Div. 3
Irwin A. Hyman (1974-76)—Div. 16
Ira Iscoe (1972-74)—Texas
Nelson F. Jones (1972-74)—Colorado
John E. Jordan (1972-74)—Div. 22
Frederick H. Kanfer (1972-74)—Div. 12
Herbert C. Kelman (1972-74)—Board of Directors
Wallace Kennedy (1974)—Georgia/North Carolina/
South Carolina/Florida
Oliver J. B. Kerner (1973-75)—Illinois
Jane W. Kessler (1973-75)—Ohio
Marc Kessler (1974-76)—Maine/New Hampshire/
Rhode Island/Vermont

¹ Terms of office have been adjusted in all cases to reflect calendar years.

Milton V. Kline (1972-74)—Div. 30
 Arthur L. Kovacs (1972-74)—Div. 29
 Leonard Krashner (1973-74)—Board of Directors
 John I. Lacey (1974-76)—Board of Directors
 Bibb Latané (1972-74)—Div. 8
 Edward E. Lawler (1973-75)—Div. 14
 Hanniah A. Levin (1972-74)—Div. 27
 James A. Lindemann (1973-75)—Oregon
 Lewis P. Lipsitt (1972-74)—Div. 7
 Kenneth B. Little (1968-77)—Executive Officer
 Frank A. Logan (1974)—Div. 3
 Joseph P. Margolin (1974)—Div. 13
 Fred Massarik (1973-75)—Div. 32
 Harry V. McNeill (1972-74)—Div. 18
 Merle L. Meacham (1972-74)—Div. 16
 Naomi M. Meara (1974-76)—Div. 17
 Nancy K. Mello (1972-74)—Div. 28
 Ronald Melzack (1973-75)—Div. 6
 Marvin Metsky (1973-75)—New Jersey
 Jack L. Michael (1973-74)—Div. 25
 Bernice L. Neugarten (1974-76)—Div. 20
 Donald P. Ogden (1973-75)—Virginia/West Virginia
 Samuel H. Osipow (1972-74)—Div. 17
 Ellis B. Page (1973-75)—Div. 15
 Robert Perloff (1974-77)—Treasurer
 Beeman N. Phillips (1973-75)—Div. 16
 Ann D. Pick (1974-76)—Div. 7
 Harold D. Proshansky (1974-76)—Div. 9
 Bertram H. Raven (1974-76)—Div. 8
 Henry D. Remple (1972-74)—Kansas
 W. W. Renke (1972-74)—Indiana
 Stanley P. Rosenzweig (1973-75)—Massachusetts
 Ivan Ross (1973-74)—Div. 23
 Herbert S. Roth (1972-74)—Iowa
 Julian B. Rotter (1974-76)—Div. 12
 S. Jay Samuels (1972-74)—Div. 15
 Theodore R. Sarbin (1972-74)—Div. 24
 Kenneth B. Schenkel (1973-75)—Georgia/North Carolina/South Carolina/Florida
 William N. Schoenfeld (1974-76)—Div. 25
 S. Don Schultz (1973-74)—California
 John W. Senders (1972-74)—Div. 21
 Max Siegel (1974-76)—Div. 29
 M. Brewster Smith (1973-75)—Board of Directors
 Janet T. Spence (1974-76)—Div. 3
 Ezra Stotland (1974)—Div. 9
 Mary L. Tenopir (1974-76)—Div. 14
 Richard F. Thompson (1974-76)—Div. 6
 Carl E. Thoresen (1972-74)—Div. 17
 Laura C. Toomey (1973-75)—Div. 31
 Ralph H. Turner (1974-76)—Div. 2
 Leona E. Tyler (1974)—Past President
 J. E. Uhlaner (1972-74)—Div. 19
 Victor H. Vroom (1973-75)—Div. 14
 Elaine C. Walster (1972-74)—Div. 8
 Gerald A. Whitmarsh (1974-76)—Maryland
 Walter H. Wilke (1972-74)—New York

Robert L. Wrenn (1973-75)—Arizona/Oklahoma
 Rogers H. Wright (1974-76)—Board of Directors

National Conference on Levels and Patterns of Professional Training in Psychology

The Major Themes

MAURICE KORMAN *University of Texas Health Science Center at Dallas*¹

Since the Chicago Conference eight years ago, American psychology has felt the effects of severe professional and social crosswinds, bringing with them serious, seemingly intractable problems. These expanding concerns and the mounting criticisms of substantial numbers of psychologists eventuated in a call for a National Conference on Levels and Patterns of Professional Training in Psychology. Supported by a grant from the National Institute of Mental Health (NIMH), the Conference took place in Vail, Colorado, July 25-30, 1973. The developments since 1965 included the following.

1. Many professional psychologists continued, even after the Chicago Conference, to express strong dissatisfaction with the apparent lack of appropriateness of training provided by many doctoral programs, their low responsivity to social issues, and their uncritical allegiance to the traditional scientist-professional model. Some of this dissatisfaction led to the formation of the National Council on Graduate Education in Psychology and found expression in new training ventures such as the Doctor of Psychology Program at the University of

Illinois and the founding of the California School of Professional Psychology.

2. Early in 1969, an Ad hoc Committee on Professional Training was created under the joint aegis of the Education and Training Board and the Board of Professional Affairs of the APA. As the Committee launched into its work under the chairmanship of John Darley, it was soon charged with additional tasks, as newly articulated problems reached the APA governance.

3. Toward the end of 1969, the Black Student Psychological Association presented the APA Council of Representatives with a number of basic demands and a plan for action. This eventuated in a program which included guidelines for the following:

(a) The recruitment of black students and black faculty members into psychology;

(b) The gathering and dissemination of information concerning the availability of various sources of financial aid for black students;

(c) The design of programs offering meaningful community experience for black students in the field of psychology;

(d) The development of terminal programs at all degree levels that would equip black students with the tools necessary to function within the black community.

4. In October 1970, the Council of Representatives began deliberations designed to insure that women would be accepted as fully enfranchised members of the profession. A Task Force on the Status of Women in Psychology was appointed for the purpose of addressing itself to three major objectives:

(a) The collection of information to document the status of women in psychology;

(b) The development of recommendations and guidelines;

¹ This summary of the deliberations of the Vail Conference was written on behalf of the Conference's Follow-Up Commission which includes the following among its members: D. W. Bray, L. D. Cohen, J. G. Darley, W. A. Hayes, T. Hilliard, E. L. Hoch, M. G. Keiffer, J. G. Kelly, M. Korman, R. B. Kurz, P. M. Lewinsohn, B. G. Little, D. P. Mejia, A. G. Ossorio, W. D. Pierce, K. E. Pottharst, A. O. Ross, G. O. Seymour, W. S. Verplanck, S. Vineberg, and J. L. White. Although the editorial wisdom of a number of the aforementioned is gratefully acknowledged, they share no blame for any inaccuracies or distortions that may be present in the report. A fuller account of the Conference's work and of the issues it confronted will appear in the Conference proceedings.

Requests for reprints should be sent to Maurice Korman, University of Texas Health Science Center at Dallas, Dallas, Texas 75235.

(c) The establishment of communications with other agencies and institutions regarding the status of women.

In its 1972 report, this Task Force made extensive proposals concerning curricula and the advising of undergraduate and graduate students; graduate training and the recruitment of women faculty members; discrimination and barriers to women in the federal government, schools, industry, and clinical practice.

5. Concern with the desirability and the implementation of less than doctoral professional training has a long (albeit undistinguished) history in organized psychology. In the last few years, additional developments revived this issue once again:

(a) Two regional conferences on the technical and professional preparation of psychologists at the master's level issued final reports strongly endorsing the MA as a professional degree based on broad psychological training and involving a potentially important role as an active agent in the community.

(b) The Education and Training Board's Task Force on Master's Level Education likewise issued a strongly worded statement proposing full APA membership status for the non-doctorally-trained psychologist and outlining an explicit program for supporting and regularizing professional master's programs.

(c) Although the Council of Representatives endorsed the Task Force's report in 1971, it reversed itself the following year, calling for a straw vote of the membership at large on some of the issues placed before it. A small segment of the APA membership voted; strong reservations were voiced regarding full APA membership for master's-level psychologists.

Such were the major concerns of organized psychology in 1971 when the Ad hoc Committee on Professional Training applied to NIMH for the necessary funds to launch a national conference on training. Shortly thereafter, a more broadly representative steering committee was convened to begin the preliminary work that led to the Conference itself.

The Vail Conference

Selection of participants lies at the heart of any conference. In this regard, Vail represented a clear departure from earlier, similar events. The steering committee sampled from a large number of prospective participants along such traditional di-

mensions as specialty, role, and area of responsibility; the committee also used criteria that resulted in the selection of 14 trainees, 40 women (including 7 from minority groups), and 29 male minority group members out of 116 invited participants.

Prior to the Conference itself, participants were assigned to 1 of 10 task groups which were provided with a specific charge summarizing the most salient, critical issues. At Vail, participants were also encouraged to form interest groups which might develop their own agendas. All conferees met in frequent plenary sessions to discuss and vote on resolutions presented by these working groups.

The end product of the Conference's five days at Vail was approximately 150 resolutions. Although some of these resolutions addressed different levels of concerns, others were too general or too specific, and still others conveyed a lack of precision with regard to priorities, it is clear that some of the same major themes are reiterated throughout the record of the Conference. These are summarized in the pages that follow.

A Professional Training Model

The Conference explicitly endorsed professional training programs as one type of heuristic model to guide those programs defining themselves by a basic service orientation. It did so *without* abandoning comprehensive psychological science as the substantive and methodological root of any educational or training enterprise in the field of psychology and *without* depreciating the value of scientist or scientist-professional training programs for certain specific objectives. It is important to view the Conference's entire work in the light of a continuing ideological commitment to the tradition of empiricism and as a clear affirmation of the fundamental importance of the scientific endeavor.

Psychology, however, is coming of age and has matured sufficiently to justify the existence of unambiguously professional programs in addition to the more traditional varieties. The choice of training model, as far as a particular program (and prospective student) is concerned, is determined by the kinds of skills its graduates will need in order to function effectively in the particular roles being chosen by and for them.

Professional programs have begun to develop in a variety of new organizational settings: medical schools; departments, schools, and colleges of educa-

tion; free-standing schools of professional psychology; autonomous professional schools in academic settings—in addition to departments of psychology in universities. Although the shaping influence of the administrative and organizational setting on program quality and effectiveness must be recognized, the Conference preferred to examine the criteria that *any* setting must meet in order to conduct high-quality professional training in psychology.

The issue of the highest professional degree label (Doctor of Philosophy versus Doctor of Psychology) was given close examination. Where primary emphasis in training is on the direct delivery of professional services and evaluation and improvement of those services, the PsyD degree is appropriate. Where primary emphasis is on the development of new knowledge in psychology, the PhD degree is appropriate. Although it is desirable to move toward uniformity of degree labels, current local administrative and political constraints must, of course, be taken into account.

Multilevel Training

In the development of professional training programs, priority must be given those that either address multiple levels of training (from the associate of arts, AA, degree to the doctorate) or at least demonstrate clear articulation with degree programs at other levels. Examples would include the development of multiple levels of training within one institutional setting or the coordination of local or regional programs at differing levels. It is clear that much waste of time and effort has resulted from poorly coordinated entrance requirements and overlapping curricula. Since the term *professional* is often narrowly reserved for the products of doctoral training, some conferees argued for a reconceptualization in terms of a *psychological service orientation*. Different services with different objectives and involving different skills can be offered to various target groups by workers at quite different levels, all of them trained in psychological skills. In our society only some of these may typically be called professionals; all of them, however, share a service orientation.

A comprehensive task analysis is urgently needed that would match the competencies for which workers are trained at each step on a service ladder with the roles, functions, and related responsibilities implied in a series of psychological tasks (e.g.,

advocate, community planner, behavior changer, evaluator, etc.).

The need for "portability" of credit for completed work was stressed, not only as it applies to movement from one level to another, but also for persons desiring to resume their education in a different location at a later point in their lives. It was recommended that heretofore indivisible courses and programs be replaced by smaller sized modules (particularly at subdoctoral levels) that would permit interchangeability and more flexible curriculum building. Credit for certain modules could be obtained on the basis of life or work experience.

The idea of a *career ladder* should be replaced by the more inclusive concept of a *career lattice*—an open-ended occupational structure which encourages broader skill acquisition at any given level in addition to upward professional movement; this would encourage continued training and development, leading to functional differentiation of skills at every performance level.

The Conference participants were concerned lest their endorsement of multilevel training systems be viewed as relegating typically disenfranchised groups such as ethnic minorities and women to "lower level" programs. It is incumbent on the "upper level" programs to set a very high priority on the recruitment of students from such groups; in addition, individuals at the lower levels of professional training should have the opportunity to receive the additional training necessary to upgrade their status.

The careful coordination of educational practices at different points on the training continuum and the encouragement of additional skill acquisition by workers at any given level were considered to be of major importance by the Conference. In fact, it was felt that the accreditation process must give very serious consideration to the degree and quality of appropriate interrelatedness among level-defined programs.

Desirable Characteristics of Professional Training

Because participants labored to a large extent in small groups, many of the resolutions adopted by the Conference as a whole dealt specifically with one or another of the three main levels of training (doctoral, master's, bachelor's and below) or with special group concerns (e.g., minority groups, women, trainees). A review of the work of the

Conference quickly established some pervasive themes, all the more remarkable because they emerged independently from the work of separate groups. Some of these conclusions are discussed below, organized around components that must be considered in a systematic evaluation of a service-oriented training program at any level.

ASSESSMENT OF CONSUMER NEEDS

In their program development (or retrenchment), trainers of psychologists must be concerned with the current job market, as well as with the long-range needs of society. It is important that current information about existing and expanding demands for psychologists in particular applied areas designed to meet societal needs lead promptly to appropriate curricular changes.

APA needs to assume a more aggressive stance in exploring and developing potential career markets for services employing individuals trained in psychology. Obvious examples abound: for example, prison psychology; psychological problems in transportation and in urban life, in population trends, and in meeting the human service needs of several underserved populations.

It was observed that more extensive and frequent interchanges of university training personnel and field psychologists would lead to a sounder perspective on new career options and potential social contributions. Arranging for fieldwork experiences in nontraditional settings will likewise sensitize students to emerging service possibilities. The potential arena of endeavor, it was felt, was nothing less than the total area of human services. Community control and consumer rights are affirmed as key service approaches; hence, consumer help in both assessing community need and in shaping program objectives is critical. Periodic monitoring with reference to the adequacy with which social needs are being met by a particular program is a necessary feature of the evaluation process. The voice of consumers of psychological services must be heard in the process of accrediting such programs.

ADMISSIONS STRATEGY

Disproportionate reliance on traditional selection criteria for professional training (e.g., grades and graduate record examination scores) has proved inadequate in providing society with a pool of socially responsive, culturally diverse, and profes-

sionally sensitive psychologists. More attention must be paid to the applicant's socially relevant experiences and goals, his or her interpersonal skills, and a variety of attitudinal and motivational factors. It is important that training programs maximize the degree of cultural diversity characterizing their students. Facilitating the admission, retention, and graduation of students from underrepresented groups will not only correct an obvious injustice, but will simultaneously add multicultural dimensions to the training context, a clearly more efficient way of preparing professionals to function in a pluralistic society.

The Conference endorsed the "truth in packaging" concept with regard to program description as necessary for intelligent decision making on the part of the student and as representing an important ethical stance on the part of the trainers. What is required is not only a clear statement of the orientation of the program and the emphasis it places on various program components and "hurdles," but also detailed information regarding specific requirements, and faculty interests and commitments. A detailed breakdown of past and present student characteristics and job placement is likewise recommended.

Programs must be prepared to accept students on a less than full-time basis; to do otherwise frequently discriminates against the older, more mature student (often the more socially committed and personally motivated trainee). Alternative life-styles and unpopular political beliefs are likewise no bar to professional training: A strong program seeks heterogeneity along many dimensions.

TRAINING STRATEGY

The Conference sought to reexamine the functional relationship between training content and the roles and activities for which it is preparing future professionals, and to do so in the light of existing social needs and ethical responsibilities. Periodic self-study is recommended to assure that nonfunctional requirements are modified or deleted.

A specific commitment to a particular training ideology or design was avoided by the Conference. It was felt that each program should capitalize on the resources available to it, seeking to become the finest possible example of the specific training and service philosophy it espoused. Nonetheless, a few guiding notions were offered:

1. Heavy emphasis was placed on field training in multiple contexts and on a concerted effort at integrating these experiences with the skills and knowledge learned in the classroom. Field experience should be consonant with the objectives of the particular program and with the unique needs and opportunities of the community.

2. The totality of settings in which professional training is provided must be congruent with the needs of a significant range of clients in a community, including persons of culturally diverse backgrounds. Psychologists have an obligation to provide services on a genuinely broad and nondiscriminatory basis. Inadequate preparation for this goal, the conferees felt, represents a shirking of an ethical obligation and does not relieve either trainer or trainee of this obligation.

3. Wherever possible, faculty and students should increase their involvement with underserved populations by providing needed services as a part of training programs. Such efforts merit funding priority from granting agencies.

4. Professional work frequently has social and political ramifications. Much that the psychologist does (or does not do) affects other individuals, his community, and society. It is important that these implications be examined and evaluated dispassionately, and training programs should provide such opportunities.

FACULTY AND TRAINEES

Faculty must provide a convincing professional role model and present a clear commitment to and expertise in the work of the applied psychologist. It is of considerable importance, therefore, that the director and senior trainers themselves be currently engaged in some form of professional work. It is in fact desirable that the training faculty maintain close and meaningful involvement with institutional or community service agencies; concomitantly, field supervisors from applied settings can strengthen the university's training base through appropriate academic appointments and through opportunities for genuine contributions to policy and decision making. The Conference further suggested periodic exchanges of faculty and field supervisors for the purpose of providing continuing professional development for both groups.

Comparable weight must be given to outstanding performance in professional training and service as is earned by distinguished empirical and theoretical endeavors. These values should have the endorse-

ment of administrators responsible for the operation and financial support of the program.

If the training faculty needs appropriate opportunities, encouragement, and rewards, so do the students. Any program that admits a student assumes a particular responsibility to maximize his or her chances of graduating. This calls for the continued availability of basic student resources: financial support, availability of counseling, non-discriminatory and noncapricious treatment, provisions for redress of grievances. Additional support systems such as adequate access to appropriate role models, relevance of curriculum, and opportunities for skill development must also be provided. It is expected that students will participate in frequent periods of self-study undertaken by the departments as a whole. They should also have a voice in shaping their own curriculum, possibly through specific academic contract.

EVALUATION AND ACCREDITATION

Considering the financial cost and human effort represented by professional education, there has been a curious lack of concern over product and program evaluation. This seems to be true of most of the major professions, but its absence is the more remarkable in a discipline that prides itself on its expertise in evaluation research.

Accreditation as currently practiced is not equal to the task of adequately evaluating the efficacy of training, the quality of graduates, and the value of the services to the ultimate recipient or the nature and significance of its impact on society. Substantially more is needed.

The Conference accepted the suggestion that a demonstration project be undertaken with the ultimate aim of revising present accreditation philosophy and procedures by focusing on the competencies of multilevel graduates and their eventual impact on society.

Samples of current graduates would undergo an intensive evaluation of their professional skills and of factors related to a readiness for ethical and productive psychological practice. Comparable data would be obtained from journeyman field psychologists at various levels of training. Finally, a broad survey would be undertaken of the careers of graduates from a wide sample of institutions in terms of the graduates' career choices and their psychological contribution to society. It is hoped that these data will contribute to a reexamination of the implicit values, beliefs, and assumptions un-

derlying training philosophies, and that this will in turn be reflected in accreditation criteria.

Additional suggestions for a revamping of the accreditation process included: (a) reiterated demands for the development and implementation of unambiguous, workable affirmative action goals, as well as timetables for increased participation of minority groups and women in the roles of students and faculty; (b) the inclusion of representatives from state psychological associations, student groups, and consumer on-site visiting teams; (c) a major restructuring and strengthening of the Education and Training Board, with special consideration being given to the possible creation of an independent accrediting body in order to fully meet these demands.

Doctoral Training

The Conference called (in the professional model) for an extensive and thoroughgoing preparation in the skills necessary for effective practice. At the same time, it concluded:

Many of the psychological services currently performed by Ph.D., Ed.D. or Psy.D. degree holders could be performed equally well by personnel trained at the master's or lower levels. The real cost of such services to the public could be appreciably lowered by training such personnel to provide them directly.

What then are the appropriate functions of the doctoral psychologist? One might conclude that while "journeyman" skills appropriately belong at the master's level (or even below), "master" professional competence should emerge with doctoral training. The Conference, however, felt that much more should be demanded of the higher level practitioner. The training of these professionals should also prepare them for the following kinds of activities: (a) evaluation of service programs and new procedures, (b) design of new service delivery systems, (c) development of new conceptual models, (d) integration of practice and theory, (e) program development and administration, (f) supervision and training.

A special contribution (or hurdle, depending on one's point of view) of the PhD student is the dissertation. The PsyD degree, on the other hand, permits appropriate substitution for the traditional dissertation. Since many institutions will, however, not be able (or willing) to shift their programs to the PsyD model, some additional suggestions were advanced by the Conference.

Flexible criteria for defining the appropriateness

of dissertation proposals are recommended in order to insure that the student's project is relevant to the professional role for which he or she is preparing. Serious consideration should also be given to the inclusion on dissertation committees of psychologists or other competent persons from field agencies and/or other campuses who may be especially qualified for such appointment. Faculty members presently excluded due to existing policies (such as those regarding tenure) should be designated as chairpersons when they represent a logical and appropriate choice.

Master's-Level Training

The position taken by the Conference on the issue of the master's degree reflected a deep concern with the legitimatization of persons trained at the master's level as psychologists and as professionals. It called for the development of strong professional master's programs (of which there are few currently), differentiated by specialization title (e.g., master's in industrial psychology), with explicitly stated objectives and with carefully integrated didactic and field training. It should be noted that this process of legitimatization rests on the restructuring of master's programs into strong, well-rounded professional training sequences.

Departments already engaged in master's training are called on to organize themselves into a Council of Professional Master's Programs and to begin the processes of disseminating curricular information and setting up standards through intensive self-review.

It was the consensus of the Conference that the properly trained master's individual has every right to be called a psychologist and should be admitted to full APA membership. In taking this position, the conferees were not unmindful of other (and potentially contradictory) concerns shared by a substantial number of professional psychologists. With the country moving toward a national health insurance system, our claim for the status of *independent* practitioner is bolstered by a definition of the psychologist as a doctoral-level professional exclusively. The conflict is a difficult one to resolve; convincing arguments can be made by both camps.

One side emphasizes the need for professional autonomy—a goal sought by every profession worthy of the name. Because of a traditional interest in preventive and developmental approaches and in

experimentation with a broad panoply of service strategies, psychology seems capable of a very unique contribution to the total health effort. Thus society, not only psychology, shall be the loser if a narrowly subservient role is assigned to it.

The other side sees dangers ahead: (a) a continuation of the inequities engendered by a fee-for-service, middle-class-oriented health system; (b) a disregard for cost control, accessibility, and availability of services, particularly where underserved target populations are concerned; and (c) a perpetuation, well into the third decade, of a serious injustice carried out at the expense of the master's-level psychologist.

The Conference could not, in good conscience, turn its back on this problem once more; it called for the inclusion of master's psychologists among its professional ranks. It did, however, reject a recommendation for their licensing or certification; such statutory implementation was left to future developments. This compromise, many participants felt, would maximize psychology's chances of becoming a clearly recognized independent profession while initiating a series of extensive, positive alterations internal to the profession with regard to master's-level professional personnel.

Training at Bachelor's Level and Below

It has become increasingly clear that many persons with less than master's-level training render a psychological service, frequently of professional caliber. Since 1966, for example, some 150 AA degree mental health programs have sprung up, typically training generalists who render a large number of services through their knowledge of specific techniques and skill in forming and maintaining human relationships. Little work has been done on carefully examining and analyzing the parameters of the sub-master's-training competencies and parallel service functions. In addition, the extent of professional psychology's responsibility toward such programs and their trainees is a generally ignored issue.

The Conference recognized two types of sub-master's programs, those that primarily emphasize academic psychology and those that include specific training in applied skills. With regard to the latter type of program, the following points were made:

1. These efforts include AA and bachelor's degree programs, as well as nondegree continuing education and skill training for various groups. Although focused primarily on mental health, other

specialties (particularly in new human services areas) represent likely possibilities for program expansion. A number of these programs produce workers with a distinctly *psychological* service orientation.

2. The Conference recognized the lack of clear information concerning manpower needs, training settings, and outcome evaluation in this area. Nonetheless, it made a number of preliminary suggestions in this context: (a) The selection process must include the evaluation of interpersonal and related skills; (b) sound field training must be a central part of all such programs; (c) some mechanism must be developed; (d) consideration must be given to affording both horizontal and lateral mobility to such trainees.

3. Are such persons psychologists? The Conference did not have a definitive answer to this question. At the very least, it was felt that the psychological establishment has some responsibility for establishing a vehicle that might provide a means for affiliation under the overall APA umbrella. It seems difficult to think of a responsible answer to many current social/professional issues that ignore this group altogether.

Continuing Professional Development

A recognition of the need for relevant continuing professional development (CPD) experiences for all professional psychologists constituted a major theme of the Conference. Not only must CPD experiences permit psychologists to update their skills in the context of a knowledge explosion and the emergence of new professional roles, but they must also facilitate career changes for psychologists wishing to prepare themselves for new functions.

A number of specific recommendations emerged, designed to facilitate the prompt implementation of CPD programs:

1. Institutions already involved in professional training are encouraged to establish or cooperate in CPD programs. Since these programs should encompass broader resources than are typically available in single instructional units, they should look to multidisciplinary content and participation.
2. Training formats must be eminently flexible because such programs often deal with part-time students. Evening sessions, one- or two-day workshops, short-term apprenticeships, cable TV, and other innovative approaches should be considered.
3. Educational institutions need to devise sys-

tems for giving "credit" for CPD participation, perhaps via "CPD units" reflecting a block of hours of participation. The convertibility of CPD units into regular academic credit would open the door to eventual completion of degree requirements for part-time students.

4. One can conceive of a series of distinct CPD offerings ranging from one-time presentations (suitable for professional psychologists wishing to stay informed about new developments) to planned sequences of educational experiences (geared to psychologists preparing themselves for new professional roles). In either case, program effectiveness must be determined by built-in evaluative mechanisms.

Professional Training and Minority Groups

The Conference's concern with the implementation of affirmative action programs—viewed as a basic ethical obligation—for the identification, recruitment, admission, and graduation of minority group students has been discussed above. In addition, the participants felt that it was important for *all* students to be prepared to function professionally in a pluralistic society. To this end, it was suggested that (a) training experience should occur in a multicultural context both within the university and in fieldwork settings; (b) the content of training must adequately prepare students for their eventual professional roles vis-à-vis a wide diversity of target groups; (c) students must be helped to maintain a balance between acculturation into a professional and scholarly role, on the one hand, and retention of their group identity and cultural sensitivity, on the other.

Because of dissatisfaction with the scope of APA's response to the concerns of ethnic minorities, the Conference accepted a resolution which recommended: (a) that a Board of Minority Advocacy, composed of representatives of ethnic minority groups, be created in APA and be responsible for examining policies touching on minority concerns; (b) that this Board have a prior review function regarding other organizational units of APA and that it advise the Board of Directors in the general area of minority affairs; (c) that an Office of Minority Affairs be created, with responsibility for monitoring and evaluating APA projects, programs, and policies, for developing and disseminating information related to minority concerns, and for initiating appropriate relationships with public and private agencies.

To the extent that federal funding continues to be a major variable in initiating training and service projects, the recommendation was made that appointments to grant review panels should parallel, through significant minority membership, the composition of target populations.

Professional Training and Women

Large numbers of well-prepared women apply for admission to graduate programs. They should be admitted at least in proportion to their numbers among the institution's applicant population. Obstacles to graduation unrelated to student performance (frequently related to family status and geographical moves) must be eliminated.

The Conference deplored the application of sex role stereotyping in the counseling and advisement tracking of undergraduate women. It was also noted that pressures on employers are creating opportunities for women in fields that heretofore were not readily open to them.

The Conference endorsed the notion that extensive empirical research is needed to examine many prevalent biases in such areas as sex role stereotyping, the definition of psychological adequacy in women, the effects of child care roles on women and men, and concepts of masculinity and femininity.

Schools and the media were singled out as institutional settings that often reflect harmful sex role stereotyping; psychologists must help modify such practices wherever they exist.

Finally, the concept of *personism* was offered as a suitable alternative to sexism. This is a term designed to reflect the awareness and acceptance of the individuality of all persons, male and female; both employers and trainers have an ethical obligation to exemplify this value in their professional behavior.

Service Delivery Systems and the Social Context

Professional training programs must develop strong linkages with service delivery systems in the community and maintain a continuing dialogue which includes the *recipients* of the services as well. It is anticipated that the introduction of the client's perspective into what then becomes a collaborative effort will significantly modify values and beliefs held by professional trainees.

Field settings present the student with a laboratory opportunity to study the interplay between

social systems and life events, as well as the parameters of system change. No other experience can drive home so forcefully the extent to which psychological distress and social dysfunction are intertwined. Ideally, a number of these community settings will be characterized by the availability of a full range of human services in addition to innovative mental health technology: job and legal counseling, welfare, vocational and physical rehabilitation, and a variety of child and family services.

The Conference alluded frequently to the fundamental importance of a problem-oriented service commitment, perhaps because society's pressing concerns with its psychological casualties demand no less of professional psychologists. At the same time, there was a definite undercurrent in what seemed to some the opposite direction: a motivation to build programs that foster and maintain human competencies and prevent dysfunction or disruption. Psychology, the conferees felt, must be fully responsive to both sets of demands, although individual psychologists may have a more focused commitment. Training opportunities should therefore encompass the full range of remediation, prevention, and development.

It is desirable that students have the opportunity to learn advocacy roles with regard to the recipients of psychological services. It is particularly those underserved populations—the poor, the aged, the prisoner, the alcoholic, and the retarded—who are the appropriate target populations for *both* service and training efforts. New service modalities designed to expand the scope of services while reducing their unit cost are badly needed. Fledgling psychologists must be sensitized to the need for the multiplicative transfer of human skills through layers of professionals, subprofessionals, and other helpers.

Evaluation of the impact of service delivery sys-

tems must take place in an interdisciplinary context, with objectives so clearly specified that their attainment or nonattainment can be adequately assessed. Finally, because of the growing disparity in quality of service between various sectors of our society, the Conference recommended that APA, together with state associations, explore the legal procedures necessary to bring about in public agencies and institutions a uniform standard of psychological service equal to that now existing in the private sector.

Conclusion

The NIMH grant which funded the Vail Conference had the unique provision of a two-year follow-up plan to disseminate as widely as possible the work of the Conference and to help initiate the process of implementation of the proposals that emerged from Vail. To that end, a Follow-Up Commission, composed of the original 10-member Steering Committee and 10 additional members chosen by the Conference participants from among themselves began to function in the waning minutes of the meeting at Vail.

The Commission continued its work at a meeting in Washington, D.C., in October 1973, where it laid plans to review and reorder the Vail resolutions along the dimensions of implementability and priority. It also decided to initiate a dialogue with all the relevant elements of the APA governance and affiliated organizations regarding the issues at hand.

The resolutions themselves were conceived of as a significant starting point in this dialogue, a deliberative explication of a certain point of view. Following consensus seeking, discussion, and feedback, it is hoped that forward-looking action plans will be developed that will quicken the emergence of American psychology into a new era of professional competence and responsivity.

Composition of the Council of Representatives

Report on Apportionment Ballot

COMMITTEE ON STRUCTURE AND FUNCTION OF COUNCIL¹

The third annual apportionment ballot held under the revised APA Bylaws dealing with the composition of Council for 1975 showed some unexpected changes from previous years. Divisions lost a total of five seats, while coalitions and state associations gained five seats. Looking behind these figures one finds that divisions fared even less well than it appears. Two new divisions appeared on the apportionment ballot for the first time. These were Division 34 (Population Psychology) and Division 35 (Psychology of Women). Division 34 failed to gain representation, while Division 35 acquired three seats on Council. Division 16 (School Psychology) was the only division improving by gaining one seat, but eight divisions each lost one seat including Division 10 (Psychology and the Arts), which lost the one seat it held. This means that, for the first time, there are now two divisions of APA (10 and 34) that do not have representation on Council. The change of five seats by coalitions and state associations is confined to just five units, two losing and three gaining. The two losing were the coalition of Utah/Wyoming/Montana/New Mexico and the Connecticut State Association, both losing their one seat on Council. The three that gained were Florida regaining the seat it lost last year, New York gaining two seats, and California gaining four seats.

Table 1 shows the ratio of Council representatives from divisions and states for the period 1966 to 1975. Under the new method of determining the composition of Council, the states appear to be faring slightly better than in the past. The gain of 4.8% by the states from 1974 to 1975 may be the result of greater efforts by the states in the last apportionment ballot, or it may be a shift representing a change in the interests of the voters. The next apportionment ballot will indicate if this is a continuing trend.

In examining the distribution of votes as shown in Table 2, it is noted that California succeeded in attracting the most 10-point allocations. Apparently, ef-

forts at convincing its members to allocate all 10 votes to California were more successful than others. Table 2 shows the obvious, that those units getting the most 10-point allocations are the ones that get the most seats on Council. This apparently says something for getting out the vote and loyalty to the division or state of your choice.

The results of the apportionment ballot are shown in Table 2. The number of members voting was 12,102, or 37.9% of the voting membership. This compares with last year's figures of 10,994 voting, or 35.2% of the voting members. These figures are normal for APA, since the percentage voting in any ballot to the membership averages between 35% and 40%.

The apportionment ballot provides for 104 Council members in 1975. This does not include members of the Board of Directors, who are members of Council in accordance with the Bylaws. Adding the 12 members of the Board brings the total on Council to 116. This total could increase if some of the units decide to form coalitions to gain representation.

Table 2 shows the changes from 1974 to 1975. Those divisions, coalitions, or states that lost seats on Council may have to arrange to recall one of their representatives in 1975 to get down to their allotted number.

TABLE 1

Division versus State Representatives, 1966-1975

Year	No. representatives from divisions	% of total	No. representatives from state associations	% of total	Total council representatives*
1966	82	73.2	30	26.8	112
1967	85	73.9	30	26.1	115
1968	94	75.2	31	24.8	125
1969	92	75.4	30	24.6	122

American Psychological Foundation

1973 Contributors

The American Psychological Foundation was established in 1953 to receive gifts from psychologists who wish to contribute to the advancement of psychology as a science and a profession in the service of knowledge and the welfare of man. Through its awards program the Foundation honors annually a senior psychologist who in his whole career has made distinguished contributions to research and scholarship (the Gold Medal Award), and it also recognizes outstanding achievements in teaching and in interpreting psychology in public media (books, newspapers, television.) Through its small grants program it supports activities of importance to psychology that would otherwise go unfunded. For example, it provides APA journals to libraries in developing nations. In addition, in appropriate cases the Foundation contributes funds to support programs of other organizations which are con-

sistent with the purposes of the Foundation.

In accordance with the Bylaws, the Foundation is placed in the hands of a Board of Trustees, consisting of the seven most recent past presidents of the APA and other members of the Association elected by the Trustees then in office.

The Foundation's program depends on the concern and generosity of psychologists. Some contribute in the form of specific cash contributions. Others assign all or part of their royalties from books, particularly books that draw heavily on the work of other psychologists. Others routinely assign income from reprinting of their papers in books of readings or other collections. Some have designated the Foundation a beneficiary in their wills. Contributions are tax deductible.

Below are listed the names of all whose contributions to the APF were received in 1973:

Sugar Bowl . . . Superdome, finished or unfinished . . . topless dancers . . . voo-doo.

And that is where the 1974 Convention of the American Psychological Association will be held. The dates of the Convention are August 30 through September 3. While August is not the ideal time to be in New Orleans, the attractions of the city should compensate for the heat and humidity. Meetings are scheduled in the Fairmont Hotel, the International Hotel, the Marriott Hotel, the Monteleone Hotel, the Royal Orleans Hotel, and the Rivergate Exhibition Center. The bulk of the Convention program is scheduled between 9:00 a.m. and 6:00 p.m. during the five days of the meeting. Because hotels are fairly close to one another, APA is not planning to run a shuttle bus among the hotels. Public transportation buses run up and down Canal Street every few minutes at a cost of 15 cents per person.

Canal Street, New Orleans' main thoroughfare, separates the French Quarter from the business district and uptown area of the city. There are historical

sights, shops, nightclubs, and restaurants within the French Quarter. In order to sample the cuisine in local restaurants it would be wise to make reservations for all meals. A handy reference on inexpensive and good restaurants is *The New Orleans Underground Gourmet* by Richard H. Collin.

Transportation from the New Orleans International Airport to the downtown area is available by taxicab or limousine. It takes about 30 minutes to make the trip. The taxicab fare is approximately \$9 plus tip for one to three persons; there is an additional charge of \$3 per person for more than three. Limousine service is available directly to the hotels at \$3 per person. Public transportation is also available from the airport for a fare of 35 cents, but it may be necessary to transfer to another bus within the city in order to get directly to your hotel. See you in New Orleans!

Housing

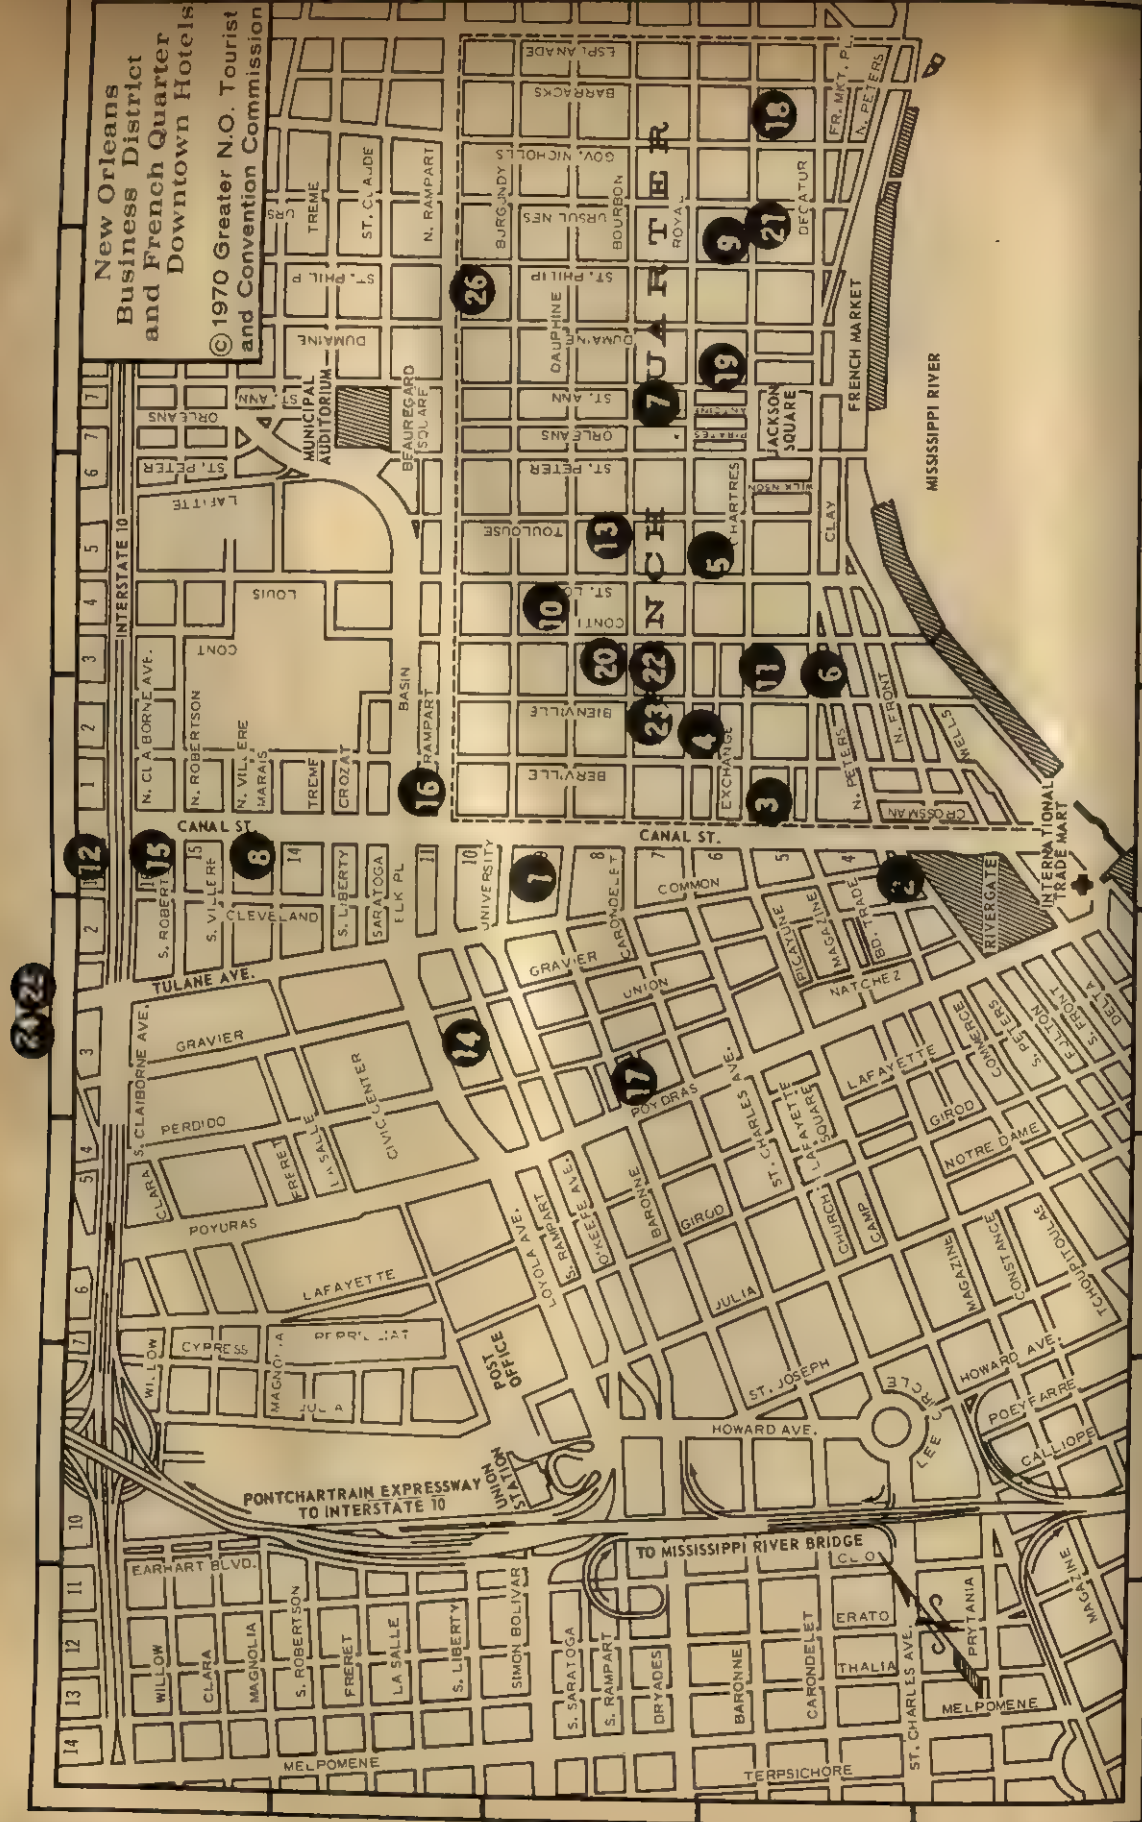

In cooperation with APA, all of the hotels have set aside, at guaranteed rates, substantial blocks of rooms. These hotels have guaranteed rates for the Convention only when registration is made through the APA Housing Bureau on the official Hotel Reservation Form. Also, these rates are guaranteed only when the Advance Registration Form and Hotel Reservation Form are returned prior to August 1, 1974. After August 1, every effort will be made to assign rooms at the guaranteed rate, but such assignments cannot be certain, and it is quite unlikely that late requests can be honored.

Members should also bear in mind that with the large number of rooms used, some members may not be assigned a room in the specific hotel they requested nor the type of room at the rate requested. It is advisable to return the Advance Registration Form and the Hotel Reservation Form as early as possible. These forms appear on pages 459-460.

All housing forms are sent from the Central Office to the New Orleans Convention Bureau for room assignments. We anticipate a three- to four-week lag between receipt of request in the APA office and your receiving confirmation from the hotel. If after four weeks you have not heard from New Orleans, please contact di-

Wheelchair Accessibility

To facilitate making hotel reservations for those people concerned with wheelchair accessibility, Division 22, the Division of Rehabilitation Psychology, compiled the following information on the accessibility of some of the Convention hotels. Wherever possible, the information has been corroborated by site visits made by knowledgeable persons. Detailed information about the accessibility of various churches, restaurants, museums, and stores may be obtained by writing for a free copy of *Guide to New Orleans for the Handicapped* from Louisiana Chapter, National Society for Crippled Children and Adults, Inc., 843 Carondelet Street, New Orleans, Louisiana 70130.

Main entrance and elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Two meet accessibility requirements and must be requested.

Monteleone Hotel

Garage entrance and three elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Hotel has 56 accessible sleeping rooms which must be specifically requested. They are rooms on the fifth floor in the following series: 53, 56, 57, 58, 63, and 69.

Fairmont Hotel

One of the main entrances to the hotel is ramped.
Public restrooms: Women's—accessible
Men's—inaccessible
Sleeping rooms: Inaccessible

Royal Orleans Hotel

Main entrance: Assistance available to negotiate the steep ramped entrance from garage and stair main entrance.
Elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Inaccessible

Marriott Hotel

Main entrance: Accessible
Elevators: Accessible
Public restrooms: Inaccessible
Sleeping rooms: Inaccessible

Royal Sonesta Hotel

Main entrance: Accessible
Elevators: Accessible
Public restrooms: Inaccessible
Sleeping rooms: Inaccessible

Persons requesting wheelchair-accessible accommodations should check the appropriate box on the Hotel Reservation Form as well as indicate the hotel and type of accommodation requested.

Registration

Convention attendees are urged to register for the meeting in advance. Not only will advance registration assist APA in planning for the meeting, but advance registration represents a saving to the registrants as well as the opportunity to obtain desired hotel space and rates. At its meeting on January 18–20, 1974, the APA Council of Representatives approved the following registration fees for the 1974 Convention:

For those registering in advance (prior to August 1, 1974):

\$30—Nonmember
\$20—APA Member, Fellow, Associate, Foreign Affiliate,
High School Teacher Affiliate

For those registering on-site in New Orleans:

\$35—Nonmember
\$25—APA Member, Fellow, Associate, Foreign Affiliate,
High School Teacher Affiliate

25. Thunderbird (Quality Inn)
26. Vieux Carre Motor Lodge

Students and other authorized exemptions from these fees appear on the Advance Registration Form.

The convention badge with name and institutional affiliation, will be mailed in advance of the Convention to those who preregister. Advance registrants will need only to obtain a badge holder at the APA registration area in New Orleans to complete the procedure—thus avoiding possible delays.

Complete member and nonmember registration facilities will be maintained at three locations: the Fairmont Hotel, the Marriott Hotel, and the Rivergate Exhibition Center—according to the following schedule:

Thursday, August 29, 8:00 p.m. to 9:00 p.m.

Friday, August 30, 8:30 a.m. to 5:30 p.m.

Saturday, August 31, 8:30 a.m. to 5:30 p.m.

From Sunday, September 1 through Tuesday, September 3, registration facilities will be available only at the Rivergate Exhibition Center. Hours will be 8:30 a.m. to 5:30 p.m. on Sunday and Monday; 8:30 a.m. to 12 noon on Tuesday.

Placement

The APA Convention Placement Office will be located in the Rivergate-South Hall. Hours will be from 9:00 a.m. to 5:00 p.m., August 30-September 3, except 1:00 p.m. closing day. Fees required are as follows:

Applicants—\$1 for reproducing (1) availability information. \$3 for use of Convention Placement facilities includes a copy of the *Position Openings Bulletin*. (Nonmembers will be charged \$20 for use of Convention Placement facilities.) July 19, 1974, is the deadline for applicant listing. Appropriate fee must accompany listing.

Employers—\$5 for reproducing (1) Job Description. \$10 for use of Convention Placement facilities includes a copy of the *Availability Notices Placement Bulletin*. July 26, 1974, is the deadline for employer listing. Appropriate fee must accompany listing.

Employers—Please note the addition of the GENERAL OPENINGS category to be used by organizations hav-

ing widespread needs for psychologists who may be recruited through a central office.

Prelisting in the more widely distributed printed booklet is encouraged, but Xerox forms will be available for on-site listing. The forms, accompanied by the appropriate listing fee, must be received by the date indicated above. Please do not include the Convention Placement facilities fee which will be collected ONLY when you register at the Placement Office. After the above date, Xerox forms will be available for listing, and requests should be directed to the address below.

A complete set of applicant availabilities will be available to employers: \$15 for each category—please indicate choice. After the Convention, order from the Convention Placement Office, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Mail orders for the printed *Availability Notices Placement Bulletin* and the *Position Openings Bulletin* are \$1.50 per copy (available August 7). Your check (no billing) may be sent to the above address.

Convention Personnel

You may wish to contact one or more of these people before or during the Convention:

Board of Convention Affairs: Carl N. Zimet, Division of Psychology, University of Colorado School of Medicine, Denver, Colorado 80220.

Convention Manager: Theodore G. Driscoll, Jr., Driscoll and Associates, 7109 Masters Drive, Potomac, Maryland 20854.

Assistant for Convention Management: Candy Won, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Convention Placement Office: Jim Beaulier, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Please Note

Meetings for Divisions 19 and 21 will be located in the *Monteleone Hotel* rather than the Royal Orleans Hotel as noted in the April convention insert.

Convention Information

1. Please indicate those APA divisions to which you belong (check one or more for list of divisions):
 Check your most senior status regardless of whether you belong to a division:
 ... **Fellow** ... **Member** ... **Associate**

2. Please indicate the number of persons who are accompanying you to this Convention but who are not completing a registration form and are not accounted for on another registration form: ... **Adults** ... **Children**

How many of them are planning to attend any meetings?

3. Please provide the address to which the convention badge is to be mailed. Be sure to fill in this space, even if it is the same as the information given elsewhere on this form.

Street Address: _____

This card and these fees are only applicable for advance registration prior to August 1, 1974. Most of the advance registration cards received in the APA Convention will have to do so on-site in New Orleans. If possible, use original forms rather than photocopied forms. Use another card for additional persons who wish to register. Additional cards can be obtained in any issue of the *American Psychologist* from April through July.

PLEASE COMPLETE BOTH SIDES OF THIS FORM.

Convention attendees are urged to register for the meeting in advance. Not only will advance registration assist APA in planning for the meeting but advance registration represents a saving to the registrant. At its January 18 to 19, 1974 meeting, the APA Council of Representatives approved the following registration fees for the 1974 Convention:

For Those Registering in Advance Prior to August 1, 1974:

\$30 Nonmember \$20 APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

For Those Registering On-Site in New Orleans:

\$35 Nonmember \$25 APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

Convention Child Care Service

Provision has been made for a professional child care service during the 1974 Convention. CON-SERV has been engaged and will offer an extensive program.

Parents desiring to use child care facilities must preregister no later than July 15, 1974. To preregister, complete the form at the bottom of this page. Please note that upon filing of the preregistration form and payment of the advance deposit as indicated on the form, CON-SERV will provide complete detailed information about the services offered and final registration materials necessary to plan for your children's comfort and safety. If for any reason your plans change, the deposit will be refunded in full if CON-SERV is notified of cancellation by August 10.

Some of the essential features of this service, as planned, are indicated below:

- The facility will be located in Braniff Place Hotel and will be open from 8:00 a.m. to 6:30 p.m., August 30–September 3, 1974. While the cost will be about \$1.50 per hour per child, APA will subsidize \$.75 of this cost. Hence, the cost to parents during the daytime will be \$.75 per hour per child.

- If there is sufficient need, the facility will remain open after 6:30 p.m. until 12 midnight to accommodate

parents who may wish to leave their children in the facility during evening hours. The parents will bear the full cost during these hours. If the need for evening child care does not justify keeping the facility open after 6:30 p.m., personnel at the facility will make every effort to help individual parents locate qualified babysitters to stay with children in their hotel rooms for those who might need this service. In any event, every effort will be made by CON-SERV to assist parents with evening child care arrangements.

- During the regular daytime hours, a variety of optional tours will also be offered at modest cost to parents. APA will subsidize part of the cost to the extent of \$.75 per hour per child as though the child were in the facility.

- In order to evaluate the child care services at past conventions, the Task Force on Convention Child Care would like you to answer the following questions: (a) What was your general reaction to past child care facilities? (b) What was the least-liked aspect? (c) What was the most-liked aspect? (d) What was needed and not provided? Please attach your answers to the preregistration form.

Preregistration Form: Child Care Service—APA Convention New Orleans, Louisiana, August 30–September 3, 1974

Preregistration form must be returned no later than July 15, 1974.

Name of Parent or Guardian: _____

Street Address: _____

City, State, Zip: _____

Name(s) of children to be registered in the child care facility:

Name	Age

_____	_____
_____	_____

If your child has a specific problem or handicap that we should be aware of, that is, speech impediment, retardation, epilepsy, etc., please let us know so that we may make the necessary provisions. _____

Please check this box if you are interested in tour information for your child

Signature of Parent or Guardian

Please return this form to Ms. Diane Snow, Con-serv, 1318 Arabella Street, New Orleans, Louisiana 70115, and enclose a check in the amount of \$7.50 for one child or \$15.00 for two or more children as listed above. Make checks payable to "Con-serv." Indicate amount enclosed:

NOTE: This is only your preregistration form. Upon receipt of this form you will be furnished complete registration materials.

Standards for Educational and Psychological Tests

1974 revision.

Developed under a grant from the Russell Sage Foundation by a joint committee of members from the APA, the American Educational Research Association, and the National Council on Measurement in Education.

This current revision of **Standards** is directed equally toward establishing guidelines for test developers and test users. It proposes *essential*, *very desirable* and *desirable* considerations for the effective development and use of standardized tests. Additionally, each standard is accompanied by an exemplary or clarifying comment. 80 pp. \$3 to APA, AERA, and NCME members; \$5 to nonmembers.

Contents:

Introduction

Standards for Tests, Manuals and Reports

Standards for Reports of Research on Reliability and Validity

Standards for the Use of Tests

To order **Standards**, send your request accompanied by full payment or institutional purchase order to:

American Psychological Association

Publication Sales Dept.

1200 17th Street, N.W.
Washington, D.C. 20036

Employers of Psychologists:

If you have or anticipate openings for psychologists, you may wish to list them with the APA Convention Placement Service. The Job Description Form below is for this purpose. Additional copies supplied upon request.

A service fee of \$5.00 per insertion will be required for listing in the **Convention Placement Bulletin**. FEE MUST ACCOMPANY COPY—no billing by APA—DEADLINE JULY 26. If you recruit at the Convention, an additional \$10.00 fee will be required for use of the Placement Office facilities. This fee payable ONLY when you register at the Placement Office.

The FINAL FORM of your job description below will be the actual copy used in photo offset printing of the **Convention Placement Bulletin**. The box thereon is the maximum space usable. An illustration and a work form are provided for your guidance. Only clean typed copy within the boundary on the FINAL FORM will be accepted for publication. Please list your job data of the kind and in the order illustrated. Do not skip any lines. Thank you.

Comment

Two Views on IQs

In December 1969, Arthur Jensen published a now famous article in the *Harvard Educational Review* entitled "How Much Can We Boost IQ and Scholastic Achievement?" In that article he put forward a number of theses about the nature of intelligence tests, their correlation with learning ability, the influence of environment on the variance in test scores, the lack of success of compensatory programs, and the causation of racial differences in performance on standardized IQ tests. Exactly two years before, in November 1967, Professor Hyde published a paper in *Educational Research* entitled "The Culturally Disadvantaged: Psychological and Educational Aspects." This article has attracted little attention. Even Jensen's thorough bibliography to his 1969 article, containing some 159 references, made no mention of this paper although, as we shall see, he had read the manuscript prior to publication. In his article, Hyde discussed many of the same issues as Jensen but came to rather different conclusions. Philosophically and methodologically it is an interesting exercise to try and determine why two qualified investigators working with much of the same data reached rather different conclusions. I shall first set out the contrasts and then provide a hypothesis to explain the differences.

The Nature of Intelligence Tests

Hyde: Standard intelligence tests, such as the Stanford-Binet and the Wechsler, are measures of specific knowledge and problem solving skills which have been acquired by the testee at some time prior to the test situation. . . . The validity of the IQ as a measure of learning ability, therefore, depends to a large extent upon equal opportunity for exposure to knowledge and skills that the test calls upon. Since intelligence

tests were originally devised to predict school performance, they call upon knowledge and cognitive skills similar to the kinds of learning required in school . . . [educability depends] upon a fund of prior knowledge, skills and acquired cognitive habits, much of which is tapped by intelligence tests [Hyde, 1967, p. 7].

Jensen: The term "intelligence" should be reserved for the rather specific meaning I have assigned to it, namely, the general factor common to standard tests of intelligence. Any one verbal definition of this factor is really inadequate, but, if we must define it in so many words, it is probably best thought of as a capacity for abstract reasoning and problem solving [Jensen, 1969, p. 19].

Thus we see Hyde pointing out the role played by the acquisition and retention of specific items of knowledge and acquired skills, and the importance of equal exposure of subjects to such items, while Jensen considers only those aspects of intelligence tests which measure the capacity for abstract reasoning and problem solving. A matter of emphasis, but as we shall see, the policy implications of the respective articles are determined precisely by what is put in the foreground and what is relegated to the background.

Correlation with Learning Ability and Test Bias

Hyde: Now, if IQ is a measure of learning rate, we should expect that learning tasks of the type used by experimental psychologists to study learning should show substantial positive correlations with IQ. This, in fact, is exactly what our research has found. . . . But here is the interesting thing: the correlation between IQ and learning ability, as measured directly in a controlled laboratory learning task, is much higher among middle-class children than among lower-class children. . . . This suggests that the IQ is almost totally unresponsive of learning ability in the low-IQ range of low socio-economic-status children. It should be noted that the majority of low socio-economic-status children are in the below-average IQ range. This is especially true for Negroes in the U.S.A. [Hyde, 1967, p. 7].

Jensen: We are finding that a unidimensional concept of intelligence is quite inadequate as a basis for understanding social class differences in ability [p. 109]. I have hypothesized two genotypically distinct basic processes underlying this continuum [of learning ability—GD], labeled Level I (associative ability) and Level II (conceptual ability) [p. 110]. In general, we find that Level I associative learning tasks correlate very substantially with IQ among middle-class children but have very low correlations with IQ among lower-class children [p. 113]. Standard IQ tests . . . tap mostly Level II ability. Thus, ordinary IQ tests are not seen as being "unfair" in the sense of yielding inaccurate or invalid measures for the many disadvantaged children who obtain low scores [Jensen, 1969, pp. 109, 110, 113, 115].

There are two usual senses of "test bias": (1) unequal predictivity in different groups and (2) measuring the intended variable less adequately in some groups than in others. Hyde argues that IQ tests are biased in Sense 1; Jensen argues that they are unbiased in Sense 2.

Environmental Influences on IQ Variance

Hyde: If the Stanford-Binet is administered to a large and truly representative example of the total population . . . we find that the distribution of IQs departs in a very systematic way from the normal Gaussian distribution. There is a bulge (i.e. excess frequency) in the lower half of the distribution, especially in the IQ range from about 65 to 90 [p. 8]. It has been hypothesized that the bulge in the lower half of the distribution of IQs is due to the proportion of the population reared under conditions which are below the threshold of those environmental influences necessary for the full development of genetic intellectual potential. Thus, presumably, if these environmental lacks were eliminated, the bulge in the distribution of IQs would be smoothed out. . . . It would be difficult to estimate precisely the average expected gain, but it is likely to be somewhere between 10 and 20 IQ points [p. 9]. Another line of evidence is quite consistent with this threshold hypothesis, namely the studies concerned with upward changes in the

IQ as a result of rather drastic environmental changes, either from "natural" causes or by means of experimental manipulation of the environment. . . . Thus, when children are removed as infants from very poor homes, in which the natural parents have subnormal IQs, and are placed in foster homes, in which the foster parents are of average or superior intelligence, the children will grow up to obtain IQs that may be from 10 to 30 points higher than would be predicted if they had been reared by their natural parents, and their educational attainments will be even higher (Skodak and Skeels, 1966) [Hyde, 1967, pp. 8, 9].

Jensen: Below a certain threshold of environmental adequacy, deprivation can have a markedly depressing effect on intelligence. . . . When I speak of subthreshold environmental deprivation, I do not refer to a mere lack of middle-class amenities. I refer to the extreme sensory and motor restrictions in environments such as those described by Skeels and Dye (1939) and Davis (1947), in which the subjects had little sensory stimulation of any kind and little contact with adults. . . . Typical culturally disadvantaged children are not reared in anything like the degree of sensory and motor deprivation that characterizes, say, the children of the Skeels study [Jensen, 1969, pp. 60-61].

Here the differences between Hyde and Jensen are extremely subtle. While they both agree on the plausibility of a threshold hypothesis, and agree that the threshold is relatively low, they nevertheless disagree as to how low it is—as can be seen from the contrasting studies that each refers to. Hyde uses as his example the Skodak and Skeels (1949) adoption study. The children involved in this study came from mothers whose average IQ was 86—below normal but not mentally retarded. The study that Jensen refers to, that of Skeels and Dye (1939), has true mothers whose average IQ was under 70—the threshold sometimes used as the borderline between mentally retarded and low normal. Thus, while it may be true that typical culturally deprived children are not reared in the degree of deprivation that is characteristic of those children involved in the Skeels and Dye study, it may be true that many are raised in homes typical of the Skodak and Skeels study. Again this is a matter of emphasis, but a

crucial one in determining whether one is optimistic or pessimistic in estimating how much IQ can be changed by environmental influences.

Racial Differences in Intelligence

Hyde: There are probably socio-economic-status differences in innate intellectual potential *within* any particular racial group, but these innate differences would be diminished to the extent that intellectually irrelevant genetic factors, such as lightness of skin color and other caucasoid features, are important as determinants of social and occupational mobility. Therefore, the fact that Negroes and Mexicans are disproportionately represented in the lower end of the socio-economic-status scale cannot be interpreted as evidence of poor genetic potential. . . . Since we know that the Negro population for the most part has suffered socio-economic and cultural disadvantages for generations past, it seems a reasonable hypothesis that their low-average IQ is due to environmental rather than to genetic factors [Hyde, 1967, p. 10].

Jensen: So all we are left with are various lines of evidence, no one of which is definitive alone, but which, viewed all together, make it a not unreasonable hypothesis that genetic factors are strongly implicated in the average Negro-white intelligence difference [Jensen, 1969, p. 82].

The difference in emphasis is obvious.

Compensatory Programs

Hyde: Finally, it must be emphasized that all educators who have worked with the disadvantaged are agreed that pre-school intervention without adequate follow-up in the first years of elementary school is inadequate, because the culturally disadvantaged child does not go home after school, as does the middle-class child, to what is essentially a tutorial situation. . . . We are gradually having to face the fact that, in order to break the cycle of poverty and cultural deprivation, the public school will have to assume for culturally disadvantaged children more of the responsibilities of good child-rearing. . . . The brutal fact is that for culturally disadvantaged children, these responsibilities are not being met. . . . [Hyde, 1967, p. 19].

Jensen: Compensatory education has been tried and it apparently has failed. . . . The chief goal of compensatory education—to remedy the educational lag of disadvantaged children and thereby narrow the achievement gap between "minority" and "majority" pupils—has been utterly unrealized in any of

the large compensatory education programs that have been evaluated so far. . . . What has gone wrong? . . . Here is where our diagnosis should begin—with the concept of the IQ. . . . [Jensen, 1969, pp. 2, 3, 5].

Given Jensen's views on IQ, and the relative fixity of the IQ, it is clear how his views of social policy will differ from those of Hyde.

What accounts for the differences between Professor Hyde and Jensen? Can it be the mere passage of time? After all, Jensen's article was written some two years later. Is it the case that we had a more adequate theory of intelligence testing in 1969 than in 1967? Did we have better learning theories in 1969 than in 1967? Did we know more about the threshold for environmental deprivation in 1969 than in 1967? Had we discovered new data on the genetic basis of black-white differences in 1969 that we were unaware of in 1967? I find this implausible.

Is it perhaps that Professor Hyde is more "intelligent" than Professor Jensen or vice versa? Certain facts about intelligence testing make this explanation unlikely.¹

In my view the best explanation for the divergence in views relies not on factors internal to the scientific discipline—such as new data or improved theories—but on the social and political climate within which the discipline functions. It is just a coincidence that 1968 (a national election year) fell between the dates of the two publications, but the election reflected changing intellectual and social currents in American society. Dissatisfaction with the accomplishments of various social welfare policies; the dim awareness that, in a society with a much reduced growth rate, issues of income distribution will be harder to handle on a consensus basis; the failure of social scientists to provide adequate predictive theories—all these issues were coming to the surface. The election

¹ Beyond age 8, correlations between repeated tests of general intelligence, corrected for unreliability of measurement, are between .9 and unity. See Bloom (1964).

transferred political power from an administration sympathetic to those theorists who promised data and hypotheses that justified the social welfare programs of the Great Society, to an administration prepared to listen to and support the work of more pessimistic and conservative theorists, and prepared to use their findings as a rationale for cutting back such social welfare programs. The time was right for the expressions of just those emphases in which Jensen's article differs from Hyde's.² I suspect, if and when a more favorable social climate develops, that Professor Hyde's contribution will be rescued from its undeserved obscurity. If this comment contributes to that end, I shall be thankful.³

The Strange Case of Dr. Jensen and Mr. Hyde?

Substantive criticism has been tried and it apparently has failed.

Probably no other single article in the history of psychological publications has been subjected to so many niggling and nit-picking commentaries in so brief a time as my essay in the *Harvard Educational Review* (HER; Jensen, 1969). (For a bibliography of 117 articles about the HER article, see Jensen, 1973b, pp. 356-364.) Now we have Dworkin's (1974) comment, which adds a new wrinkle by pointing out some changes of position or emphasis between one of my articles published in 1967 and the HER article of 1969. Ascribing the HER article to Jensen and the pre-HER article to Hyde is a most novel twist indeed. One is used to seeing it the other way around.

Views and conclusions based on ideological dogma, it is true, should not be expected to change. But on the frontiers of an empirical science, why should anyone be surprised if an investigator's hypotheses, interpretations, and emphases show some changes over a two-year period? Any differences in this respect between my 1967 and 1969 articles simply reflect the results of my continuing study of the matters in question. As any scientist, my thinking is influenced by the research of others and by the results of my own investigations, which, since 1967, have involved the testing by me and my assistants of more than 15,000 children. When I wrote the 1967 article the extremely important Coleman Report had not yet appeared, nor the nationwide survey of compensatory education programs by the U.S. Commission on Civil Rights. A number of studies related to my Level I-Level II theory of mental abilities were undertaken between 1967 and 1969. The evolution of my thinking during this period is clearly reflected in several of my pre-HER articles (e.g., Jensen, 1968a, 1968b, 1968c, 1968d). Between the 1967 and 1969 articles I spent a year at the Center for Advanced Study in the Behav-

ioral Sciences, which provided the opportunity to delve more thoroughly into the literature on the genetics of mental abilities. I had actually gone there with plans for a book on the psychology of the culturally disadvantaged, a book I conceived of as an elaboration of my 1967 article (Jensen, 1967). But the further I studied the research literature of the 1960s on the causes of individual differences in mental abilities and scholastic achievement, the more clearly it appeared to me that the doctrinaire disparagement of genetic thinking, and even more often the complete neglect of genetics in the study of human differences related to educability, amounted to a corruption of behavioral science by social ideology. I have always regarded behavioral science as continuous with biology.

I doubt that the changes in my views between 1967 and 1969 are of any greater magnitude or are essentially different in character than are the changes that can be noted in any other two-year period of my research career, which I have chronicled elsewhere (Jensen, 1974c). One should have no difficulty noting the continuing changes of a similar nature throughout my writings since the HER article: (a) I have been led to a clearer distinction between learning ability and intelligence by my continuing investigations and modifications of the Level I-Level II theory of mental abilities and of the interaction of Levels I and II with social class and race (Jensen, 1970, 1971, 1973e, 1974b); (b) the notion of the environmental threshold in intellectual development, first expressed in 1967, has undergone modifications in light of evidence, criticism, and parsimony in theoretical formulation, because the same phenomenon can be explained without this concept and in terms of a simpler model of genetic and environmental influences (Jensen, 1973a, pp. 175-179); (c) my studies of culture bias in mental tests have led me to disbelieve the most popular explanations of certain ethnic group and social class differences in IQ (Jensen, in press); (d) I have summarized the evidence that

has led me to even greater doubts than I had in 1969 about purely environmental explanations of particular racial and social class differences in intelligence (Jensen, 1973a, 1973f); (e) my 1967 interpretation of the Skodak and Skeels (1949) study did not have the benefit of my reanalysis of their original data by the methods of quantitative genetics (Jensen, 1973d); (f) measures such as Head Start, performance contracting, and busing to achieve racial balance, in light of studies since 1969, appear to me now less promising as means of improving education than at the time I wrote the *HER* article. Consequently, I have since put more emphasis on taking account of developmental readiness for school learning and on diversified educational programs in accord with individual differences in abilities (Jensen, 1973b, 1974a).

Finally, I believe that psychology can develop as a science only as it stays clear of subservience to political ideologies. I will continue to deplore any trends to the contrary.

Further Comment on the Risky Shift

A comment on Dorwin Cartwright's (March 1973) article is, by the Journal's formal rules, no longer timely. But because I saw letters on the subject in the December 1973 issue, and because my own primary reaction to this research has not been re-

flected in anything I have read, I will make my reaction explicit and brief.

I think my chapter "Group Dynamics" in *Social Psychology* (Brown, 1965) bears some responsibility for having made risky shift experiments popular for a time among young social psychologists. In fact, I have read only a small part of the risky shift literature because my main work leaves little time for this reading. Cartwright's article seems to make its points in a scholarly, gentle fashion, and I have no quarrel with it. However, there is an important idea here, much more abstract than the risky shift, which, as far as I know, has been largely overlooked.

In *Social Psychology*, the term *risky shift* was not used because it is an incorrect nominalization for the phenomenon in question. What happens is that people usually make advance, private recommendations of action to a hypothetical *other* person in a particular set of story problems which are less risky than the recommendations made by group consensus after the group convenes, all private positions are made known, and often there is a discussion of the story problem. As far as I can see, there is no risk in the shift. It is not a shift that is risky to the persons making it, but rather a shift to recommendations involving greater risk than the central tendency of the original recommendations. Better, then, to say "shift to increased risk" phenomenon, but obviously it is not worth writing a letter to criticize the choice of a name for a phenomenon. Neither is it worthwhile making the defensive observation that the phenomenon was used in *Social Psychology* simply as a concrete example around which to build a discussion of thinking about group dynamics. What follows is, perhaps, worth a letter.

The explanation of the term *shift to increased risk*, which the chapter in my *Social Psychology* particularly favored, is as follows: For a certain set of story problems, certainly not all, most Americans probably think it desirable to be a bit more audacious

or risky than the average person. A degree of derring-do is probably valued when your advisee takes most of the burden of the risks on himself. Let us suppose that is true: that it is considered a virtue, or good quality, to be fairly, but not wildly, risky in certain situations by a majority of Americans, perhaps especially young ones. Giving advice in private, then, each participant means to be somewhat audacious. But how can he know *how* to be so since the situations and options are novel and invented? He cannot know what the average person would do. After the group has convened and each individual has made known his private recommendation, the central tendency can then be estimated and, therefore, the way the average person behaves calculated. Thus, in arriving at a group consensus, or at new individual recommendations, those who have in fact been exceptionally conservative or just average, but who *meant* to be audacious, will feel inclined to favor a new recommendation riskier than their first recommendations. It should also be true that those whose first recommendations turn out to be absurdly or wildly risky would feel some inclination to get closer to the central tendency, though still above it. The net result with just the right story problems and action options will be a shift to increased risk from the central tendency of initial private recommendations to the recommendation on which the group agrees or which is obtained a second time, from each person alone. The basic idea is that knowledge of a distribution of options, taken for a completely new situation, teaches one how to *realize* or make manifest the value he held all along.

I think *Social Psychology* did not make it clear enough that the interesting problem is not the existence or nonexistence of a risky shift. Quite obviously, from the data reported in the book, some story problems cause a shift to increased caution. But it is the abstract process, conceived in terms neither of risk nor caution alone, that is really interesting. The suggestion is that just as there are

many situations in which individuals will be motivated to conform, to huddle up close to the central tendency (as in perceptual judgments), there is another class of situations in which people will be motivated to fall on one or the other side of the central tendency because they seek not to be average but better than average, or virtuous. To be virtuous, in any of an indefinite number of dimensions, is to be different from the mean—in the right direction and to the right degree.

Imagine if you can, though it is certainly false, that everyone who contributes to his community's annual united charities drive means to be "generous." In fact, of course, very many individuals give as little as they can get away with, or give only as much as is respectable (conformists). But suppose not. Then the question arises: How do you go about manifesting generosity in this situation? What *do* most people of your economic bracket give to the United Fund? I certainly don't know. Harvard University does not publish any sort of distribution of contributions made—probably wisely so because I suspect many would feel more inclined to be "fiscally cautious" than generous. But suppose this were a situation in which just the same value, *generosity*, were predominantly activated in everyone, and the facts were confidential so that no one knew how to be generous, which is a relative thing after all. If we recorded our intentions in private and in ignorance, and then recorded them again after full disclosure of the intentions of whatever group we take as a point of reference, should there not be a shift to increased generosity, a "generosity shift"? Incidentally, and obviously, it would depend in part on whether contributions were to be published or confidential.

It is the abstract class of cases that I think is interesting, not the risky shift. Suppose people do want to be, in some situations, more than average honest, truthful, sexually faithful, or whatever, but not so much more so as to risk canonization. How do they go about learning

what to do? What are the central tendencies for cheating on one's income tax? Behaving with patriotic courage as a prisoner of war? Being scrupulous in the administration of research grants? I think this general class of problem—manifesting reasonable virtue—is at least as general and important as the conformity problem. This problem of virtue is very timely since judicial and congressional inquiries and empirical studies of sexual behavior are providing more information about actual behavior distributions in some areas than has previously been available—and are often generating surprise. The cry for "openness" on whatever level creates a need to know some of the probable consequences of increased openness.

As it has happened, researchers have not themselves been very audacious but have, most of them, stayed close to the original design. The studies multiplied, and so it came to seem as if the interesting problem was whether a risky shift exists, rather than the laws determining how one manifests a value or virtue in completely novel circumstances, which includes most circumstances. The risky shift, as such, is rather discontinuous with social-psychological theory generally and seems scarcely worth the effort and ingenuity devoted to it. In addition, the research story has become complicated and full of seeming contradictions, and psychology has wearied of it as it has wearied of many other problems when they reached this stage. In turning away from the risky shift, it would be a great pity if we also turned away from the abstract problem, which has simply not been represented adequately in the literature. The problem of learning from groups how to manifest in concrete situations the virtues or values one holds is important, timely, and perfectly continuous with social psychology generally.

If, in what I have said, I have overlooked someone's research report or shown ignorance of a published theoretical statement, then I apologize and admit to ignorance but not.

deliberate slight. I have not, in my limited reading, come across what I think are the essential abstract issues, and it would be sad if psychology declared a vast important terrain out of fashion or trivial just because one small tract in that expanse may have grown tiresome.

Comment on Gergen

I should like to comment on the article by Gergen (October 1973). It is a basic contravention of human rights and human dignity to argue that we can set aside the possible effects of research procedures on humans until they are demonstrated to be harmful. If this attitude "reflects [in Gergen's words] only the historically dependent sentiments of but one segment of the plurality," so be it.

Gergen's attitude is similar to that of a client of mine who countered my objection to his failure to provide for informed consent with the remark, "If I tell them what I'm doing, they won't let me do it."

Gergen is entitled to investigate in an ethical fashion whether or not various research practices do indeed have their purported effects. The outcomes of such experiments do not bear on the ethical question. Ethical principles and standards are not held on such a contingent basis. One has regard for the rights of others quite independently of whether they have regard for their own rights, or for one's own for that matter.

Thomas. *American Psychologist*, 1974, 28, 907-912.

ARTHUR F. JOHNSON
Veterans Administration Center
Hines, Illinois

The Civil Liberties of the Participants in Psychological Research

Gergen (October 1973) contends that psychologists should make use of experimental techniques to identify the consequences which result both from behaving in accordance with the various ethical principles and from violating them during the course of psychological research. "If subjects remain unaffected by variations along these dimensions, then the establishment of the principles becomes highly questionable [p. 907]." What is missing from Gergen's analyses is any consideration of the personal rights of individual research participants. Such selective inattention should not be permitted to continue.

From Gergen's statements I infer that, if research on the consequences of adhering or not adhering to a particular principle yields results which show the null hypothesis to be tenable, then he would have no objection to the violation of that principle. I will leave aside the question of whether this research should be conducted prior to establishing a principle (as Gergen recommends) or whether it should constitute a means of evaluating an already established principle. In either case, it should be recognized that before conclusions could be drawn, it would be necessary that all relevant outcome variables be identified and studied. A violation of an ethical principle which does not affect a person's anxiety level as measured on a pencil-and-paper test may change his physiological responses; a violation which does not affect reported hostility toward the experimenter may change the subject's trust in others. The short-term consequences of a procedure

may differ widely from the long-term consequences of the same procedure. The task Gergen proposes is virtually limitless. In addition, it would be necessary that steps be taken to minimize the occurrence of β errors since the consequences of failing to identify a true difference between the conditions are of such gravity. How would an "acceptable" level of error be determined?

My primary concern with Gergen's proposal is not with the methodological difficulties inhering in it but with the view Gergen has of the civil rights of research participants. Gergen wishes to consider research subjects as a class possessing certain right as a class. He believes that if damage can be demonstrated to the class as a whole, then an ethical principle should be observed. He misunderstands the nature of civil liberties. Rights belong to individuals not to collectives. When a violation of rights occurs, it is some individual who suffers, not some abstract conceptual grouping. By continually referring to "subjects" as if they were an undifferentiated group, Gergen obscures the fact that each participant is a distinct individual entitled to the full protection of his rights. Even if no statistically significant effects of violating an ethical principle can be identified, the failure to adhere to the principle could still entail the violation of the personal rights of individual research subjects.

Consider a research project to evaluate the effects of adhering to or violating the principle of informed consent with respect to the inducing of a negative self-concept. The condition showing adherence to the principle would involve role playing while the other condition would entail deception. It may well be that a substantial majority of the subjects whose informed consent was not obtained actually enjoy their participation in the study and believe that they have benefited from finding out about their own gullibility. At the same time, a very small minority of the participants may be-

come disturbed by the experience and resent the deception that resulted in their participation in the study. The overall outcome of comparing the informed and noninformed groups may not yield a significant difference because the benefit to some subjects balances out the harm done to others. But note that the harm that ensues from the study is experienced by individuals, not by a collective termed "subjects."

What of those subjects who were harmed? It is of no solace to them to know that most people were not harmed by the research or even that "a significant increment in knowledge" was achieved from the study. A person does not lose his rights because others were not harmed by their participation under similar conditions.

Consideration of the civil liberties of research participants has been much more extensive in the field of medicine than in the field of psychology. The Nuremberg Military Tribunal drafted a code on medical experimentation on human beings (*United States v. Karl Brandt*), and the World Medical Association has issued the Declaration of Helsinki on the subject (Katz, 1972). The Nuremberg Code contains the following statement:

The voluntary consent of the human subject is absolutely essential. This means that the person involved should have legal capacity to give consent; should be so situated as to be able to exercise free power of choice, without the intervention of any element of force, fraud, deceit, duress, over-reaching, or other ulterior form of constraint or coercion; and should have sufficient knowledge and comprehension of the elements of the subject matter involved so to enable him to make an understanding and enlightened decision. This latter element requires that before the acceptance of an affirmative decision by the experimental subject there should be made known to him the nature, duration, and purpose of the experiment; the method and means by which it is to be conducted; all inconveniences and hazards reasonably to be expected; and the effects upon his health or person which may possibly come from his participation in the experiment (Katz, 1972, p. 305).

It is not sufficient for a physician to inform a research subject that on the average no harm is done by a particular procedure; he has an obligation to inform each individual participant of any possible negative outcomes that could reasonably be foreseen. If a researcher fails to do this he is subject to legal penalties. He may be sued for the recovery of any losses incurred as a result of the research and may, in addition, be sued for punitive damages.

There are very good reasons to believe that the same legal conditions which apply to medical research also apply to psychological research. A person does not waive any of his personal rights when he becomes a subject in a psychological study. The legal prohibitions on negligence, reckless endangerment, and fraud apply with full force in the relationship between a psychological experimenter and research participant. If a psychologist has any reason to believe that physical or psychological harm may result from participation in an experiment, then he has a legal, as well as an ethical, obligation to inform the prospective participant. It may be just a matter of time before this matter is tested in the courts, if, indeed, this has not already occurred.

Gergen's lack of concern with personal rights is to a large degree shared by the members of the Ad hoc Committee on Ethical Standards in Psychological Research (1973) who drafted the statement of ethical principles. Consideration is given to the aim of contributing to psychological science and to human welfare and concern is expressed over preserving the dignity and welfare of research participants. However, the personal rights of research subjects are seen as violable at the researcher's discretion. For example, in a discussion of mental stress the following sentence appears: "It must be ascertained that the importance of the research justifies the level of stress likely to be involved, and, where possible, the informed participant as well as the investigator must

agree that such is the case [p. 70, *italics added*]." A subject in a study in which unanticipated stress was employed who experienced any damages as a result of his participation would have good legal grounds on which to sue the experimenter, no matter how important the particular research project.

The American Psychological Association may, for its own purposes, adopt a code of research ethics, but this in no way lessens the responsibility of the researcher to observe legal safeguards. A psychologist who is a defendant in a damage suit will not find himself absolved simply because he has followed the ethical principles endorsed by the Association, if at the same time he has violated the civil rights of the plaintiff. Psychologists must recognize that they are subject to the rule of law and to legal penalties. They ignore the civil liberties of research participants at their own peril.

Back Into Silk Purses

While in agreement with many of the specific points made by Bersoff (October 1973), I disagree with most of his conclusions and deplore the general tone of his article. In other words, I admire the cloth he has chosen to remake the "silk purse," but I am critical of the stitching.

I agree with the following points: (a) General intelligence testing should be replaced by "psychositu-

control mechanism for controlling classroom experience. Ideal Mr. Bernoff not merely has written on diagnostic uses of the TAT, but on its uses as predictors of classroom behavior. The Thematic Apperception Test (TAT) as a tool for adequate assessment of an individual's emotional range and ego resources. c. Projective tests are good predictors of specific behavior and outcome.

On the other hand I disagree with the following Bernoff generalizations: a. Psychologists and other psychodynamically oriented practitioners tend to a theory that views the human as relatively independent of the situation in which the person is embedded (p. 297). The word "relatively" is ambiguous. If it means "relative to behavior theory" then I take no issue with Bernoff's point. However, if it means "relative to the situation" then I think that Bernoff is guilty of at the most ignorance of Schuler's (1964) chapter on the test situation. b. I also disagree with the implication that traditional psychological tests in general and projective tests in particular are not "theoretical." Anyone who has had experience with projective techniques such as the Rorschach and TAT must appreciate the descriptive nature of the test results because truly proper and test protocols and human personality states can be described by the same phraseology. No two are alike" (c). I disagree with the conclusion that projective techniques should be considered in terms of "projective, relational, nonverbal" or other techniques that are more "theoretical" and better at prediction. General better prediction is an important if not essential goal for psychologists, but understanding an individual's emotional, psychodynamic, and ego resources while and with change is about having the kind of personality description that is far from predictive techniques. d. The moderate arrival and human personality and ego resources are the dominant trait more than

the individual's specific reaction to a specific situation. His point here is that we know so much of what the individual brings to each situation in the package commonly referred to as "personality." I perceive that a divide between psychodynamical assessment and traditional projective testing is an error for the ultimate in predictive and descriptive testing. I am sure Dr. Bernoff for the evidence suggests that the "considering psychodynamical or projective testing and mediating structure and mechanism" (Waller, 1964, p. 147) does indeed exist and calling it names will not make it go away or change in importance. If projective testing is eliminated then I believe that psychological assessment will be at the very least no better off than before and at the most hopelessly inferior.

On Bernoff's "Milk Purser"

Bernoff's (1964, 1971) comments on the domain and use of projective testing is not a matter of no doubt and some doubt about which I find well taken and pointed but in the context of what appears to be a gross lack of familiarity with the fundamentals, principles of psychodynamical psychological testing for the reason some of his specific statements require a response. For they lead to a basic conceptual cloud which is by no means minor.

Only a small and which is, in my view, a very small part of the problem.

Now, I suspect, would question Bernoff's observation that "the measure something" (1964, p. 297) is closely related to a capacity to be intelligently and creatively with the demands of the real world. The "IQ" tests are only measures of a narrow range of ability. Psychodynamically viewed, they are a crude and crude manner of thinking a characteristic way of operating when faced with tasks requiring a solution that is (1) creative and (2) innovative and quantitative. This however is a minor point. More important is Bernoff's notion that "because psychological testing (traditionally) occurs in an 'artificial' setting, it is of limited relevance" (1964, p. 297) to other contexts is highly speculative. Further, he suggests that "testers" (and not to be aware of the extent of contextual influences upon test performance. While it may be unwise for me to speak for others, these contentions fly in the face of what psychodynamic (testers are typically taught and hopefully learn about the instruments that they use. Psychodynamic test data are not to be examined in a vacuum (although Bernoff may be right that this is an ideal which we only imperfectly live up to), but rather occur in an interpersonal and interpretational matrix which must be noted and integrated into test findings. Presumably, then, with a psychodynamic orientation will, for example, take into account the likelihood that an individual referred for testing because he is a behavior problem in school will approach and participate in testing differently than an individual referred because he is being considered for an executive business position. Standard tests on psychodynamic testing (Allison, Blatt, & Zimer, 1964; Schuler, 1964) devote much attention to precisely these issues.

Another related misconception about the contextual factors in testing comes up in Bernoff's description of the TAT. He seems amazed at the "unpredictability" of test results which would make something of a "milk

the student research project, focusing on what is going on in the world, is a very new development. It is not, as you have just said, just a tool which says that one should not have been as part of their research, certainly teach to change in their research practice, while conducting their studies, in that they try to make their relationship with powerful participants something other than a pure show of power, but just, of the spirit of the ethical standards is that researchers have a moral obligation to try to achieve their goals.

Since the Headstart of all child study was concerned as research about ethical research and would as part it to have been particularly sensitive to such issues. Indeed it might to have been the outcome of

100-46-101-2000) in connection with the treatment of deceased participants. It is therefore interesting that (a) the defendant was charged by mail, since such an inexpensive medium provides the opportunity for restoring the quality of the relationship with the experimenter after the deception occurred, and (b) the researchers apparently made no effort to discover if the participants learned anything as a result of their participation in the study.

A final point which ought to be noted is that, in a study concerned with ethical standards the researchers neither forced nor discouraged the participants in their recruitment of research participants via awarding of course credits a technique which the Committee on Ethical Standards has termed substantially coercive.

Psychology in Action

NEW SOVIET RESEARCH INSTITUTE OF PSYCHOLOGY

A MILESTONE IN THE DEVELOPMENT OF PSYCHOLOGY IN THE USSR

JOSEF BROZEK *Lodz University**

LUCIANO MECACCI *Institute of Psychology
National Research Council, Rome*

The decision in December 1971 to form an Institute of Psychology attached to the USSR Academy of Sciences was a major event in the recent history of Soviet psychology. The formation of the Institute is comparable in significance to such milestones as the establishment in 1927 of a psychological journal (*Voprosy psichologii*), after a lapse of some 20 years; the foundation in 1927 of the Soviet Psychological Society; the convening in Moscow of the 16th International Congress of Psychology in 1966; the establishment of a Faculty of Psychology in 1966-1967 at the University of Moscow and Leningrad; and the 1968 decree of the Council of Ministers of the USSR which permitted awarding advanced degrees in the field of "psychological sciences" (Brozek, 1970, 1972).

The Institute is a visible indicator of recognition, at the highest level, of the advances made by Soviet psychology. With Il'f Lomov (in January 28, 1972) as Director of the Institute, the younger generation of Soviet psychologists is coming to the forefront.

The intent stressed by Lomov to pay special attention to "the structure of contemporary scientific psychology and the trends in its development is in keeping with the open-mindedness and absorptive capacity demonstrated in the 1950s by Lomov as Director of the Laboratory of Engineering Psychology at the Leningrad State University.

The new scientific center is to become the leading Soviet research establishment in the fields of general

experimental, social, industrial, and engineering psychology. The Institute's research programs will include not only psychology but also representations of other disciplines such as physiology and medicine.

As a result of the distinct role of the scientific academy, the administrative structure of Soviet research differs so radically from the American pattern that it may be useful to examine the history of the new Institute of Psychology within a broader history of psychology.

The Place of Academies in the Soviet Institutional Setting

Gole and Maltzman (1969) expressed studies the "culture shock" experienced by Western psychologists first encountering the Soviet scene. Learning about Soviet psychology and psychological physiology for the first time is a little like Darwin first visiting the Galapagos. Different forms of species have evolved as a result of isolation and interbreeding (p. 3).

This applies also to the organizational structure of psychology. While the Soviet Union encompasses Moscow, Leningrad, Kiev, Tbilisi, and other important centers of research, in the Soviet system the leading functions of universities are basically restricted. Research is the primary responsibility of the academies.

The organizational structure of the Soviet system of research academies is complex. We shall in this article have primarily with the Academy of Sciences and review only the academies of the other five republics even though some of the issues are relevant. For an ample, the thorough Academy of Sciences in Tbilisi includes the psychiatric D. N. Ananashvili Institute of Psychology directed by A. N. Prizhevskii.

The highest scientific organ of the Soviet Union, the Soviet Academy of the Soviet Academy of Sciences, have to the Academy of Sciences is established by Peter the Great in 1724. Kopylov & Kopylov (1964)

* Much of the background information for this article was obtained during exchange fellowships with the USSR Academy of Sciences arranged by the National Academy of Sciences, the Josef Brozek and by the Consiglio Nazionale delle Ricerche for Luciano Mecacci.

psychological phenomena, their synthesis, and the generalization of the findings, consideration will be given to the mutual relations between different fields of psychology cultivated at the Institute and to the ways in which they are "locked" into the general theory of psychology. A dependable general-theoretical basis will increase the effectiveness of the special branches of scientific psychology. The psychology to be pursued at the Institute is viewed as a comprehensive, coherent system dealing with man's activities in the areas of cognition, work, and communication. Heavy emphasis is being placed by Lomov on the need for close cooperation with other scientific disciplines and with other institutions of the Academy of Sciences.

In the humanities ("philosophical sciences," according to the Russian usage), psychological research is expected to contribute a creative approach to such problems as the role of the individual—the "subjective factor"—in historical processes, in mass movements, and in the organization and management of society but also in the generation of knowledge.

Among the problems at the interface of psychology and the "concrete social sciences" are noted the investigation of social groups, including the collectives of workers; increased productivity of workers; management of economic, sociopolitical, and cultural processes and ideological efforts; education, personality, and society, and psychological aspects of law, ethics, and aesthetics.

Psychology interacts with the complex of biological sciences, especially with the physiology of the human organism, its development, and the regulation of its functions, including "higher nervous activity" (conditioning), sensation, and speech. Modeling of mental functions brings psychology into contact with cybernetics.

Psychology is involved in the different aspects of the "man and technology" complex, for example, the interaction between the human operator and electronic computers, and exploration of outer space, including the selection and training of astronauts.

In summary, in Lomov's view, the principal responsibilities of the Institute will involve (a) basic research in psychology and provision of the theoretical foundations of applied psychology; (b) participation in interdisciplinary ("complex") investigations involving the "human factor," as in research on space travel and industrial work; (c) research required for the formulation of long-range plans for the development of psychology in the Soviet Union; and (d) advanced training of scientific personnel in selected specialties of psychology.

A LOOK AT BRITISH GRADUATE STUDENTS

THOMAS I. DE VOL *University of Missouri-Columbia*¹

The most recent survey of psychology training programs in the United Kingdom was conducted by Arthur Summerfield at Birkbeck College, University of London, in 1965 for the American Psychological Association (APA) and the International Union of Psychological Science (IUPS, 1966). The present survey was undertaken to identify critical student enrollment characteristics that were not surveyed by Summerfield. These characteristics included total postgraduate enrollment, doctoral student enrollment, age at entry into and graduation from doctoral-level training programs, and minority group representation.

A general survey form was constructed for the present purpose and mailed with a cover letter and return postage in late 1972 and early 1973 to 89 departments offering advanced courses and/or supervision for research leading to the PhD with a major in one or more subspecialties of psychology. The 89 departments were identified through three sources: the APA (1966), the British Psychological Society (1972), and the (British) Social Science Research Council (1972). Departments that failed to issue survey responses within 90 days were sent reminders.

Findings will be discussed in reference to comparable American survey findings. A total of 34 (38%) surveys were returned at various levels of completion. In a number of instances respondents representing small departments or newly established graduate programs were unable to provide accurate estimates of many of the statistics they were asked to report. In addition, two would-be respondents representing established university departments refused to provide any information.

General Enrollment

Thirty-four departments issued enrollment data for all postbaccalaureate psychology students. The total en-

rollment for these departments combined was 1,112. Only 277 of these students were enrolled in PhD programs. An estimate of total United Kingdom psychology graduate student enrollment was made by taking the average(s) for each of the departments that reported enrollment data and multiplying this by the total number of known United Kingdom postgraduate psychology training programs. The average for all postgraduate programs combined was 38.3. This figure times the total number of departments (89) yielded a projected total enrollment of 3,408.² A comparable projection based on El-Khawas and Astin's (1972) survey of 297 (89%) departments in the United States offering postgraduate training in psychology yielded a total enrollment figure 8.4 times the United Kingdom estimate: 28,737 (\bar{X} 86.04 \times 334 programs). Since the population of England, Wales, Scotland, and Northern Ireland is at least one fourth that of the United States (55,347,000; William Clowes & Sons Limited, 1973), it is not possible to discount the smaller United Kingdom postgraduate enrollment as a direct function of a smaller population base. With this taken into consideration it is compelling to assume that psychology as a discipline is not supported by the British to the same degree that it is supported by Americans. An even greater discrepancy exists between the two countries at the doctoral level. The ratio here is 14.2:1 favoring the United States. (United Kingdom: \bar{X} 9.56 \times 89 programs = 814; United States: \bar{X} 92.92 \times 125 programs = 11,615 [Khanna & Khanna, 1972]). Two factors that figure heavily in the very small doctoral enrollment in the United Kingdom are (a) full recognition of master's- or diploma-level psychologists given by the Department of Health and Social Security and the British Psychological Society (BPS, 1972) and (b) British tutorial training by research only at the doctoral level. In a number of cases, only one or two PhD students were listed. Certainly, no question can be raised about the quality of doctoral training in these departments. Given the shrinking job market for PhDs in this country along with major drawbacks inherent in

¹ The author is indebted to Sherman Ross, former Director of the International Opportunities for Advanced Training and Research in Psychology Project, and Richard Thoreson, American Visiting Professor, Reading University, for their timely advice, and to Robert S. Daniel, Professor of Psychology, University of Missouri, for supervising the project.

Requests for reprints should be sent to Thomas I. De Vol, Counseling Psychology Section (183 W), Veterans Administration Hospital, 10701 East Boulevard, Cleveland, Ohio 44106.

² This and other projections should be accepted with caution. The colleges, universities, and technical schools from whom responses were obtained selected themselves into the sample. It is possible, for instance, that a disproportionate share of larger departments selected themselves into the sample. If this were the case, estimates of total enrollment would be inflated.

"mass producing" PhDs (e.g., Khanna & Khanna, 1972, critique of the American comprehensive examination), the English tutorial system may be given increasing attention in the not too distant future by American educators.

Age at Entry and Graduation

The mean age of beginning doctoral students was 23.58 and the mean age at graduation was 26.7 ($N_{\text{departments}} = 24$). Pressey (1965) reported a median age for graduation of PhD students in this country of 31. Pressey (1965) also sampled APA presidents and other renowned American psychologists and found an early age pattern close to the figure typifying the British and the Irish: APA presidents: $Mdn = 25.7$ ($N = 25$); E. L. Thorndike, 23; Kohler, 22; etc. Pressey concluded from his findings that we do a disservice to students by extending their education past the age of 26. The fact that the British are able to graduate half of their PhD psychologists at age 26 and younger suggests that Pressey's position is as realistic (feasible) as it is desirable.

It may be concluded on the bases of the present survey and comparable domestic survey data that (a) United Kingdom postgraduate training in psychology (at both beginning and advanced levels) is conducted on a much smaller scale than in the United States, (b) United Kingdom students enter doctoral training at an early age and typically graduate at a much earlier age than students in this country, and (c) females and nonwhite minority groups are well represented in doctoral training programs in the United Kingdom.

Minority Representation

WOMEN

Approximately 30% (30.5%) of the students registered for doctoral study were female ($N_{\text{programs}} = 18$). El-Khawas and Astin (1972) reported that women comprised 40% of their sample of all graduate students (MAs and PhDs) in the United States. Thus, on the surface at least, it appears that females are not represented in the United Kingdom to the degree they are in the United States. However, if a survey of female doctoral students only were to be taken in this country it might well show a much smaller percentage of females (El-Khawas & Astin, 1972). An informal tally of new (1973) APA members (who it may be assumed are recent American university PhD recipients) taken by the writer, for instance, revealed that women were outnumbered by men roughly three to one ($417 \pm \text{women}/1,742_{\text{total}}$).

NONWHITE

Eighteen departments provided estimates of the percentage of nonwhites enrolled in their respective doctoral programs. The mean percentage for these departments (combined) was 3.72, falling 3.28 percentage points short of the combined MA and PhD nonwhite enrollment in this country (El-Khawas & Astin, 1972). Here again the possibility that such figures are not comparable presents itself. Furthermore, it may well be that there are fewer nonwhites in the United Kingdom population as a whole than in the United States. Unfortunately, the United Kingdom census bureau does not issue official statistics for minority classifications (Central Statistical Office, 1970).

Predoctoral, Doctoral, and Postdoctoral Programs

Adelphi University Postdoctoral Program in Psychotherapy: Now accepting applications for admission for fall semester 1974. The Program in the Institute of Advanced Psychological Studies is a four-year curriculum in psychoanalysis and psychotherapy encompassing personal therapy, supervision, academic courses, and seminars and research. The Program also announces a two-year specialty program in group therapy, beginning in the fall 1974. A

PhD in psychology and two years of postdoctoral psychotherapy training are requisites for admission. For further information and applications for either program write to Donald S. Milman, Codirector, Postdoctoral Program in Psychotherapy, Institute of Advanced Psychological Studies, Adelphi University, Garden City, New York 11530. When requesting information, please specify which program.

Edward W. Cook School of Parapsychiatry: Announces a professional development program leading to a master's degree in counseling and psychotherapy, awarded by Antioch College. The program establishes a new profession, that of parapsychiatry. A parapsychiatrist is a professional mental health worker trained in the diagnosis and treatment of psychiatric disorders in adolescents. The parapsychiatrist works under the supervision of a consulting psychiatrist. Two full years of training are required for completion of the master's degree program: an 18-month practical and didactic curriculum and a 6-month internship. The program is oriented toward the achievement of competency in four basic areas: academic, diagnostic, treatment skills, and sociotherapeutic techniques. The academic framework is basically psychoanalytic, and the graduate will be qualified to practice psychotherapy as part of a mental health team. Interested persons should write to the Office of the Provost, Constance Bultman Wilson Center for Education and Psychiatry, Faribault, Minnesota 55021.

Elmcrest Psychiatric Institute: Now accepting applications for pre- and postdoctoral internships in clinical psychology. The Institute is an expanding inpatient mental health fa-

cility with emphasis on intensive therapeutic community. It offers supervised experience and seminar teaching of group therapy, individual therapy, psychodrama, and psychological testing. There is a special focus on family therapy and multiple family group therapy. Interns have the opportunity to explore their interests in art therapy and movement therapy. The Program is flexible and can be adapted to the needs and interests of the individual. Stipends are available. Send application and vita to Fredda S. Kelly, Elmcrest Psychiatric Institute, 25 Marlborough Street, Portland, Connecticut 06480.

Indiana University School of Medicine: Announces a postdoctoral fellowship in clinical child psychology with advanced training in diagnosis and treatment of children, adolescents, and families; school and community consultation; developmental disabilities; neuropsychology; research; and supervision. The fellowship is for one or two years. The stipend is \$8,500, plus \$600 per dependent, \$3,600 of which is tax exempt. Applicants must have a doctorate in clinical psychology and a clinical internship. The fellowship can start at any time. For further information write to Aare Truumaa, Section of Psychology, Department of Psychiatry, Indiana University School of Medicine, Indianapolis, Indiana 46202.

National Institute for the Psychotherapies: Announces an innovative training program in psychotherapy. It is now accepting applications for its certificate program in comprehensive psychotherapy for fall 1974. The Institute, chartered by the Regents of the State of New York, offers a unique, psychodynamically based training program, which, over four years of part-time study, provides integrated, elective instruction in the major psychotherapeutic modalities, for example, analysis, behavior therapy, Gestalt. Eligibility is limited to qualified psychiatrists, psychologists, social workers, and psy-

chiatric nurses. For further information write to Kenneth Frank, Codirector of Training, National Institute for the Psychotherapies, Suite 200, 330 West 58th Street, New York, New York 10019.

Piedmont Summer Program, Wake Forest University: Announces its three-week residential workshop for professionals who wish to expand their group leadership skills, June 23 through July 14, 1974, in Winston-Salem, North Carolina. Active participation in training sessions and coleading a weekend growth group provide an experiential focus. Graduate credit is available. Drawing upon the varied resources of psychotherapy, counseling, and the human potentials movement, study includes training in personal awareness and interpersonal skills, transactional analysis, Gestalt techniques, experiential teaching, family therapy, human sexuality, psychodrama, T-group procedures, leadership dynamics and ethics, body movement, yoga, expressive art, and other body-minded procedures. For further information write to John Woodmansee, Piedmont Summer Program, Wake Forest University, P.O. Box 6129, Winston-Salem, North Carolina 27109.

Postdoctoral Research Training, Department of Psychiatry, Montefiore Hospital and Medical Center: Fellowship positions are available through National Institute of Mental Health-supported programs that provide basic preparation for research in areas relevant to mental health and brain and behavior. The Program is available to individuals who have completed the requirements for a doctorate degree. Emphasis is on acquiring proficiency in the fundamental principles of research strategy, methodology, and techniques currently employed in laboratory and clinical studies in psychiatry. The traineeships stress active participation in research work under the supervision of faculty preceptors, supplemented by a curriculum of seminars and workshops. For further

information write to Herbert Weiner, Department of Psychiatry, Montefiore Hospital and Medical Center, 111 East 210th Street, Bronx, New York 10467.

APF Journal Subscription Grants

American Psychological Foundation Journal Subscription Grants: Funds are available from the American Psychological Foundation for APA journal subscription grants to postdoctoral foreign students trained in American and Canadian universities and now residing in their native lands. These grants, limited in number, are intended for centers that are interested in developing local research and scholarship but that lack financial resources for such purposes. The subscription awards will cover the cost of approximately five APA journals. Applicants would choose any five from a complete list of APA journals.¹ Each grant will run for a five-year period. Applications can be made by any foreign university, college, or research center in the form of a letter to Harry C. Triandis, Department of Psychology, University of Illinois, Champaign, Illinois, 61820, USA, and should include assurances to the APF Committee that (a) the journals would be made available to undergraduate and graduate students as well as faculty, (b) the journals would be controlled by a librarian at an educational or research institution, and (c) there is a need for outside assistance of this sort.

¹ *American Psychologist, Contemporary Psychology, Developmental Psychology, Journal of Abnormal Psychology, Journal of Applied Psychology, Journal of Comparative and Physiological Psychology, Journal of Consulting Psychology, Journal of Counseling Psychology, Journal of Educational Psychology, Journal of Experimental Psychology, Journal of Personality and Social Psychology, Professional Psychology, Psychological Abstracts, Psychological Bulletin, and Psychological Review.*

MALE HOMOSEXUALS

THEIR PROBLEMS AND ADAPTATIONS
BY MARTIN S. WEINBERG
AND COLIN J. WILLIAMS

Drawing on interviews with over 2400 homosexuals in San Francisco, New York, Amsterdam, and Copenhagen, Weinberg and Williams present a picture of how a male adjusts to the social structures and values that surround him after he identifies himself as a homosexual. The authors reject the once-common illness model and view their subjects in the context of societal reaction theory, an approach through which they discredit a number of popular stereotypes and offer a positive program of action for alleviating the problems the homosexual faces. "An important study, careful in its conclusions, and with significant implications."—Judd Marmor, M.D. Vice President, American Psychiatric Assn., 1972-73.

**What is he trying
to tell you?**

Quite a lot, according to author and professor of psychology Claire Golomb.

But not necessarily what we have come to expect.

Her study of 300 children, from two to seven, challenges many widely accepted beliefs concerning children's capacities and intentions in their representations of the human figure.

The first study to include children's three-dimensional modeling, it is also the only one that permits the systematic comparison of their drawing and modeling.

The book is richly illustrated with the children's drawings and photographs of their sculpture.

The knowledge explosion. This Lockheed tool helps you tame it and tap it.

Keeping pace with the outpouring of the world's best scientific and medical minds has been almost impossible. The data base, Psychological Abstracts, alone has 125,000 abstracts.

Now Lockheed's Dialog retrieval system offers you a low-cost, easy-to-use way of controlling and tapping this deluge of information. With Dialog, the world's most important data bases—such as Psychological Abstracts, AIM/ARM and ERIC—can be searched for as little as \$10. Or even less.

In minutes, Dialog can help keep you from reinventing the wheel. Or pinpoint published work that will be helpful to you in your achievements.

Dialog is easy to use. It only takes a terminal and a telephone. And it only takes a letter or a phone call to get more information. Contact Barbara Ellis, (415) 493-4411, Ext. 45635, Dept. 15-50, Bldg. 201, 3251 Hanover St., Palo Alto, Ca. 94304. In Washington, D.C., phone R. Caputo, (202) 872-5971; in New York, R. Donati, (212) 682-4630.

DEPRESSION

causes
and
treatment

Aaron T. Beck, M.D.

Interestingly written, highly informative, well documented, and of high scientific quality. . . . It makes an important contribution to the psychology of depression. . . . Since depression is a treatable disorder, and one whose diagnosis is not always clear, this is a book which should be read by every medical student and psychiatric resident as well as by psychiatrists already in practice.

—John M. Davis, M.D., *American Journal of Psychiatry*

Appraisals of this breadth are hard to find. It will be valuable to research workers and clinicians alike, and it well deserves recognition as a classic text.

—*British Journal of Social and Clinical Psychology*

This volume without doubt transcends all previous writings on depression.

—*International Journal of Group Psychotherapy*

**Now available in a paperback edition
for students at only \$4.45!**

Also available in cloth: \$12.50.

A publication of the University of Pennsylvania Press.

This is a most valuable book which, in readable style, has developed an excellent overview of the syndrome.

—*Psychiatry Digest*

It is well-written, clear, free of jargon, and interesting. His ambitious efforts have made it the most impressive recent work on depression.

—*Annals of Internal Medicine*

Can be characterized by the most positive adjectives one might think of in evaluating a book in medicine or psychiatry.

—*Bulletin of Suicidology*

A welcome addition to the clinician's library and a reference source for graduate students studying psychopathology.

—*Contemporary Psychology*

A most stimulating and useful text.

—*Psychosomatic Medicine*

The principal work on the subject and a valuable source of reference.

—J. R. M. Copeland, M.D., *British Journal of Psychiatry*

Excellent and much needed study of depression, which will be particularly useful to students of abnormal psychology in university departments, and also to clinical psychologists.

—*British Journal of Psychology*

The best book I know of on the subject, with the right mixture of the psychiatric and psychological approaches.

—Paul E. Meehl, Ph.D., *University of Minnesota*

I have found Dr. Beck's book extremely useful in classes and extremely useful in connection with research in this field because of its encyclopedic nature.

—Joseph Zubin, Ph.D.

Undoubtedly the most comprehensive, sophisticated and original work on depression that has appeared in years . . . Beck's contribution is to add a new dimension to the psychodynamics of depression. His book introduces a radical shift of focus . . . to the cognitive organization underlying self-esteem and depression. . . . It amply lives up to the promise of comprehensiveness contained in its title.

—Myer Mendelson, M.D., *Psychiatry and Social Science Book Review*

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions. Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the Journal, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this Journal may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness.

Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

And Still the Dryads Linger

ROBERT L. EBEL *Michigan State University*¹

The title of this article was borrowed in part from that of another presidential address which was given more than 40 years ago. The speaker was Paul R. Heyl, a scientist and philosopher on the staff of the U.S. Bureau of Standards. The occasion was a meeting of the Philosophical Society of Washington, D.C., of which Heyl was president. He called his address "The Lingering Dryad" (Heyl, 1930). Here is some of what he said at the start of it:

The dryad was a tree nymph. Every tree had its protecting spirit who was born with the tree, lived in or near it in intimate association, watching over its growth, and who died when the tree fell. The dryad was thus a personification of the life of the tree, and the connection between nymph and tree was far more intimate than was the case with the deities dominating sea or wind. Because of this peculiarly intimate relation the tree possessed life which the sea did not, though Neptune inhabited its depths, and which the wind did not, though set in motion by Aeolus.

The men of old, it seems, drew very much the same distinction that we do when we speak of living and nonliving substances. Water, they observed, never grew old or died, but a tree was obviously a living thing, almost one of us, growing, reproducing its kind, and eventually dying. And as the ancients had difficulty in forming an idea of life without an animating personality there arose naturally the concept of the inseparable tree nymph.

Human thinking from the first has been frankly anthropomorphic. Only in modern times has there been any notable effort to cast out anthropomorphism from our philosophy, and this struggle has not yet resulted in victory. Even we of today, with hereditary habits of thought heavy upon us, find the concept of impersonal, physical causes drab and unsatisfying, and we spell Nature with a capital N. The dryad lingers [pp. 205-206].

Thus spoke Paul Heyl in his presidential address 40 years ago. He went on to discuss the debate in biology between the mechanists and the vitalists, between those who put their faith in natural causes and those who believed that supernatural influences must have been involved in some way in the crea-

tion of life from nonliving matter, and later in giving some living forms the powers of reflective thought and the guidance of conscience. He traced the steady advance of the mechanists, the steady retreat of the vitalists. First to go were the ancient gods of the physical world, Aeolus, Neptune, Poseidon, and the rest, along with their junior partners, the fairies, elves, demons, and dryads. All of these are now consigned to the realms of mythology by most of us. Then, a century and a half ago, the vitalists lost an important battle. Friedrich Woehler heated the inorganic compound ammonium cyanate and transformed it into the organic compound urea. The supposed barrier between living and nonliving matter, between organic and inorganic chemistry, was breached.

Biochemists in our day have gone much farther. They seem to be approaching the goal of creating primitive particles of living matter out of nonliving materials. Success may elude them for a while, but few scientists doubt that the goal will be attained ultimately (Fox, 1960).

Dryads of the Mind

Thus in the physical world today there is less room for supernatural influences than there used to be. There are fewer homes for dryads. But in the world of the mind, some of them still seem to lurk in the woods and thickets. Of course they are not called dryads. Those who speak with scholarly care call them hypothetical constructs. Sometimes they are called traits (Allport, 1966). More often they are not regarded as members of any class. Those who accept them as real and important do not inquire too closely what stuff they may be made of. But they are cherished because they seem to explain why different people behave in different ways. To those who enjoy mystery, the fogs of vagueness that surround them do more to augment than to diminish respect for them. Mystery, they believe, is what one ought to expect when one is dealing with ultimate essences.

¹ This article was the presidential address presented to Division 5 at the meeting of the American Psychological Association, Honolulu, Hawaii, September 1972.

Requests for reprints should be sent to Robert L. Ebel, College of Education, Michigan State University, East Lansing, Michigan 48823.

The history of these dryads is a long one. Originally they were thought to dwell not just in the brain but throughout the whole body. There were four humors—blood, phlegm, yellow bile, and black bile—that were held responsible for the behavioral manifestations of cheerfulness, impassivity, irritability, and melancholy, respectively. A person's behavior in a particular instance, as well as his general temperament, were attributed to the relative abundance or potency of these four humors in his body. There was, of course, nothing dryadic about these four substances. They were, with one possible exception, tangible, observable substances. Dryads enter the picture in the hypothetical influence of these substances on behavior and temperament.

Later on, as the mind took up residence principally in the brain, the dryads reappeared in the guise of mental faculties: attention, perception, memory, reasoning, imagination, will power, and the like. These faculties were regarded as general powers of the mind, gifts of a favored inheritance, or fruits of a disciplined education. Phrenologists made a pseudoprofession out of attempts to discover relationships between the shape of a person's skull and the degree of over- or underdevelopment of the various mental faculties.

The humors of our ancestors have been replaced to some extent by hormones, much more numerous and more limited and specific in their relation to body processes and behavior. But we no longer have much faith in the ancient humors, in skull contours, or in mental faculties as determiners of behavior. Those particular dryads are pretty well gone, so far as most of us are concerned. But others have appeared to take their place. They have gained acceptance in some of the best circles of behavioral science. To question them is to invite an argument, but I believe they need to be questioned. When they are used simply to describe behavior they are soundly meaningful, and I have no quarrel with them. But when they are used to explain the behavior, they take on all of the questionable characteristics of the dryads of long ago.

What is meant by "explain" in this context is to account for a specific instance in terms of a general law of the type: if-then always. Such laws relate a sufficient cause to its invariable effect (Reichenbach, 1951). The "sufficient causes" called into question here as dryads of the mind are traits originating as descriptions of behavior, but

then coming to be accepted as explanations of the behavior.

Here are three prominent examples of contemporary mental dryads:

Intelligence, when the term is used to explain rapid learning or effective behavior.

Motivation, when the term is used to explain persistent efforts to succeed.

Creativity, when the term is used to explain production of an original work.

Am I saying that there is no meaning in words such as intelligence, or motivation, or creativity; that there are no important differences among people in how easily they learn or how quickly they understand, in how hard they work to reach a particular goal, in how successfully they innovate? No indeed! I am no more inclined to make such absurd claims than I would be to deny that trees live, winds blow, or storms trouble the seas. What I do say is that to attribute these differences in learning, effort, or innovation to differences in the intelligence, motivation, or creativity of the person involved is to go well beyond any credible evidence, to create the illusion of explanation in the absence of any real explanation, and to forestall or misdirect efforts to achieve real understanding. It is to invoke the help of dryads to explain away what we do not understand.

The only evidence we have that a person is more or less intelligent is that he behaves more or less intelligently. To say that he behaves intelligently *because* he possesses intelligence is completely circular (Cureton, 1951). The only evidence we have that a person is highly motivated is that he works hard to achieve a goal. To say that he works hard *because* he is highly motivated is completely circular. The only evidence we have of a person's creativity is the quality of his creations. To say that he creates effectively *because* of his creativity is completely circular. Careful psychologists are no doubt aware of this kind of circularity and do their best to avoid it. But when hypothetical constructs are used to explain observed behavior, it is very difficult to avoid. Not all psychologists manage to do it, and many in the public who read of their hypothetical speculations are quite unaware of the danger.

In none of these cases do we have any evidence for the existence or nature of the presumed cause apart from the effect it is supposed to produce. On this score the ancients who believed in the four

humors, or the more recent phrenologists, were a step ahead of us. They were probably wrong in thinking that anger was caused by an excess of yellow bile, melancholy by an excess of black bile, or curiosity by a particular bump on the head. But at least they had presumed causes that could be observed independently of the effects they produced. With intelligence, motivation, and creativity we do not. We have no more reason to believe in them than our ancestors had to believe in dryads. In all of these cases we are dealing with purely hypothetical causes of observable phenomena.

Intelligence, motivation, and creativity, when used not to describe but to explain behavior, are hypothetical constructs. There is nothing wrong with hypothetical constructs per se. Physical scientists have made good use of many of them. Universal gravitation is one. The luminiferous ether is another. The electron is a third. The gene is a fourth. What is wrong with intelligence, motivation, and creativity is that they are bad hypothetical constructs—ad hoc, imprecise, unverifiable. Their only function is to dispose of the question "Why?" without providing any real answer to it.

Good hypothetical constructs are precisely defined. Expected functional relations between them and observable variables are specified exactly so that they can be tested experimentally. In short, the hypothetical constructs useful to the scientist imply relations between different phenomena. They are not unique, ad hoc, "explanatory" hypotheses, as intelligence, motivation, and creativity appear to be.

Intelligence as an Explanatory Construct

Consider intelligence as an explanation of rapid learning or effective behavior (McNemar, 1964). What is it? Presumably it might be a consequence of some special anatomical or physiological quality of the brain or nervous system. Since human beings differ anatomically and physiologically in other respects, it is reasonable to guess they differ in neural qualities also. But no such differences have been discovered among normal human beings. What is more serious, the concept of intelligence as a cause is not even related to any hypotheses about neuroanatomy or neurophysiology by most people who use the term. It is simply a description of behavior that many accept as an explanation of that behavior.

A number of other dryads of the mind are associated with intelligence as explanations of behavior. There are higher mental processes, cognitive skills, and cognitive strategies among others. It may be worthwhile to consider each of these briefly.

Part of the difficulty with the term *higher mental processes* is in seeing the difference between higher and lower mental processes. Is recall a lower mental process? When I leave the office and try to recall where my car was parked the last time I left it, in Lot D, H, M, or P, and where in the lot, it seems that I am using about all the mental processes, high and low, that I possess. Further, because we do not really know what a mental process is, may it not be premature to try to differentiate higher and lower mental processes?

To Charles H. Judd (1936) and some of his associates and successors, particularly at the University of Chicago, the essence of education was cultivation of the higher mental processes. Gagné (1968) emphasized the development of cognitive skills and cognitive strategies. In both cases there is an effort to separate the process of thinking from the content of the thoughts and to give priority to the process over the content in specifying the objectives of education. It seems to me that such separation is impossible (Ebel, 1972a, 1972b). As I consider what goes on in schools and colleges, I find few instances in which processes of thinking are taught separately from the content to be thought about. Reviewing my own education, it seems that I always learned process and content together: in reading, arithmetic, and grammar; in Latin, geometry, and physics; in measurement, statistics, and philosophy. That is why in my own teaching I do not try mainly to develop abstract cognitive skills in my students, or to cultivate abstract higher mental processes. Instead I try to help them build solid, comprehensive structures of knowledge. Of course, these structures include knowing how to do, as well as knowing what is so. But the emphasis is squarely on knowing.

A reader who thinks critically as he reads may inquire at this point whether "structure of knowledge" is not as much of a dryad as "higher mental processes," "cognitive skills," or "cognitive strategies." Is it not like them a hypothetical construct? Indeed it is, but it differs significantly from the others in this important respect: It is more clearly and specifically definable than they usually have been. Further, and partly as a consequence of this,

others better, utilize our human resources more effectively, or if not these, at least accept more philosophically our limitations and peculiarities and those of our fellowmen. But human behavior is also a complex phenomenon, something that is likely to be difficult to understand. We need to recognize that words describing behavior, words like *intelligent*, or *motivated*, or *creative*, cannot be transformed by the wave of a linguistic wand into explanations of that behavior. We need to recognize that explanation of behavior requires more than suggestion of a hypothetical cause for it. The hypothetical cause must be verified as a real cause. It must be shown to have construct validity. This means, as a minimum, that it is a measurable quantitative variable that is functionally related to some variable or variables other than the behavior variable it presumably explains.

The Validation of Physical and Behavioral Constructs

Validated constructs are abundant in the physical and biological sciences. Few dryads linger there. They have been replaced by less purely hypothetical, more completely validated constructs. The dryads of phlogiston and the philosopher's stone, of caloric and the ether, of spontaneous generation and the inheritance of acquired characteristics have been replaced by the validated constructs of oxidation and nuclear reactions, of molecular motion and empty space, of reproduction and mutation.

In the behavioral sciences, on the other hand, dryads like those mentioned earlier in this article, seem to linger in larger numbers and greater security. Why is this true? Is it because the constructs that might replace dryads are more difficult to validate in the behavioral sciences than in the physical sciences? It seems clear that the number of precisely defined, readily quantifiable constructs is much smaller in the domain of behavior than it is in natural science. This difficulty may be due, in turn, to the greater complexity of behavioral phenomena. Contrast the very large number of precise functional relations among the physical constructs with the very small number of such relations among behavioral constructs. On the border between physiology and psychology, in the field of sensory psychology, a number of precise, quantitative relations have been discovered. But as one moves farther from biology toward behavior, considering problems of learning and thinking, of

motivation and adjustment, of personality and social behavior, precise quantitative relations become fewer and fewer. Look in a compilation of the laws of human behavior as provided in the book by Berelson and Steiner (1964). While much useful data from specific studies are reported, the "laws" themselves are disappointing. Few are precise statements of exact quantitative relations.

To validate an explanatory construct one must show that it is functionally related to some behavioral variable rather than the one it was invoked to explain. This means that it must be defined clearly enough to allow it to be measured with a high degree of reliability. It also must be defined in sufficiently basic terms so that the construct can be expected to have some general utility. Behavioral scientists do not need to be reminded that few if any explanatory constructs have been defined so as to meet both of these requirements.

Inadequately defined constructs typically yield very imprecise functional relations. Few, if any, of them can be expressed in mathematical formulas. Many are expressed as correlation coefficients, usually far from unity. Sometimes a "functional relationship" is considered to have been established on no better basis than that the correlation between the two variables cannot be attributed wholly to chance.

Low correlations between functionally related variables may be due to imprecise measurements of the variables. They may also be due to the influence on the dependent variable of many other independent variables not measured or even considered in studying the relationship. Probably both factors are responsible for the low correlations observed in most studies of functionally related behavior variables.

Can these defects be remedied? Do they exist mainly because the behavioral sciences are "younger" than the physical and biological sciences? Perhaps. On the other hand, behavioral science may be less well developed than astronomy, physics, chemistry, or biology because it presents harder problems to solve, not because it was neglected so long. From the record of history it appears that man has been concerned about problems of human behavior just as long as, and probably more seriously than, he has been concerned about problems in his natural environment. A more plausible explanation may be that the phenomena studied by the behavioral scientist involve many more variables that are much more com-

plexly related. Perhaps it is not just a matter of time until we have as impressive an array of clearly defined and broadly useful variables and precisely powerful functional relationships in the behavioral sciences as we have in the physical sciences. That day may never come (Bakan, 1972).

The most precise and useful scientific laws deal with relationships in which the number of variables involved is relatively small and the relations among them relatively simple (e.g., $e = mc^2$, $I = E/R$, $s = \frac{1}{2}at^2$, $F = ma$). These situations are quite common in basic physical phenomena. They become less common as the situations to which they are expected to apply become more complex. The variables that affect the functioning of a living cell are infinitely more numerous and more complexly related than those that affect the swings of a pendulum or the orbital motions of a planet. There are physical variables of temperature, pressure, motion, electric potentials, and electromagnetic radiations which affect the cell. There are chemical variables in the protoplasm of the cell and its inclusions, in the hormones, nutrients, and metabolic wastes in the fluids surrounding the cell. There are structural variables in the cell wall, cell body, and the nucleus; in the chromosomes, centrioles, nucleolus, Golgi bodies, and many other structural features. There are genetic variables in the arrangement of bases that carry the genetic code in nucleic acid. Is it reasonable to believe that the functioning of a cell ought to be as easy to understand and predict as the functioning of a pendulum? Since the variables that affect the behavior of a person are infinitely more numerous and complex than those that affect the functioning of a living cell, it is not difficult to see why scientific understanding of human behavior comes hard and slowly (Van Den Haag, 1959).

Why is it that the occurrence of an eclipse can be predicted 10 years hence, or 100 years hence, with much greater certainty and precision than tomorrow's weather? It is because the variables involved in the eclipse are much fewer and their functional relations much simpler. In principle, tomorrow's weather is as predictable as a twenty-first-century eclipse. It is fully determined by atmospheric circulation, which in turn depends in general on heat exchange and the rotation of the earth, and in particular on surface features of the earth.

In practice, as everyone knows, weather predictions are fraught with uncertainty. The most

plausible explanation for this uncertainty is that there are just too many variables involved, and their functional relations are too complex, too nonlinear (Kovach, 1960), too sensitive to minute changes. Given better data on the status of the earth's atmosphere today and more complete and accurate knowledge of the physics of the atmosphere and the influence of the local terrain, better weather forecasts could be made. But modest increases in the accuracy of the forecasts cost increasingly large amounts of money and effort. There comes a point when the increase in accuracy may not be worth what it is likely to cost.

What seems to be true of laws dealing with weather phenomena may also be true of the laws of human behavior. They may involve so many variables in such complex relationships as to be very difficult to discover. They may have such limited ranges of application and be so ephemeral as to be hardly worth the effort of discovery. For human beings learn, and with this learning comes changes in their behavior. What is true of the individual is also true of the race. Conditions of life change and bring with them changes in needs, values, and patterns of behavior. In these circumstances it is not easy to discover laws of behavior that will have enduring general validity.

Hence, we cannot expect that the valid constructs of behavioral science will dispose of dryads of the mind as quickly and decisively as those of natural science have disposed of its dryads. But this need not keep us from recognizing our dryads for what they are—partial descriptions that may quagrade as causal explanations. This need not keep us from understanding how useless they are in our search for understanding of behavioral phenomena. Let us be on guard against their deceptive pretensions. Let us make behavioral science, limited and imperfect as it is, inhospitable to them. They can only weaken it. Let them linger, if they must, outside of our houses of intellect.

How Do You Know?

FRED ATTNEAVE *University of Oregon*¹

Epistemology is traditionally classified as one of the fields of philosophy, and some psychologists have been content to leave it to the philosophers. In my opinion, the problem of how we know is an absolutely basic concern of psychology, but whether you consider my remarks to be psychology or philosophy I really do not care, as long as you are willing to grant me that the problem is a fundamental one.

Naively, it seems to us that the outside world, the world around us, is a given; it is just there. I look out and see you sitting in front of me; around you I see walls that enclose the room and stop me from seeing farther. But my world, the world I live in, does not seem to stop at the walls; beyond them, in the same continuous space, there are cities, roads, rivers, oceans, all of which have some determinate loci in my picture of the world. We all feel as if our experiencing of the world around us were quite direct. However, the apparent immediacy of this experience *has* to be more or less illusory because we know that every bit of our information about external things is coming in through our sense organs, or has come in through our sense organs at some time in the past. All of it, to the best of our knowledge, is mediated by receptor activity and is relayed to the brain in the form of Morse code signals, as it were, so that what we experience as the "real world," and locate outside ourselves, cannot possibly be anything better than a *representation* of the external world. (Epistemologists can argue about whether it is even that, but I am willing to take for granted the existence of a physical world that is being represented.) The afferent nerve impulses that link the representation to the reality are extraordinarily dissimilar to either, however formally considered. This is the point of Brunswik's (1952) *lens analogy*: information about

the world is represented in a very diffuse way at the receptor level, but is brought to a "focus" within the nervous system where objects and events are presumably represented in a form more "like" the outside world than they are at the receptor surface.

The statement that the world as we know it is a representation is, I think, a truism—there is really no way it can be wrong. It has some fairly interesting corollaries, however, that you may or may not have contemplated. One of them is that I have got to be at least as complex as the world as I know it, and psychologists who are attracted by simplistic theories might do well to ask themselves whether they are taking this fact seriously.

We can say in the first place, then, that knowing necessarily involves representation. Now what does "representation" mean? To say that one system represents another, we must at least mean that certain parts and relations between parts of one system must, via some sort of transformation, *correspond* to certain parts and relations between parts of the other system. This is not necessarily to say, however, that the correspondence has to be part for part and relation for relation. Another important possibility, which I shall discuss presently, is that what is a relation in one system may be a part, or an element, in the other. It just makes for a more complicated transformation if that is true.

Let us consider two representational systems that we know something about, and that exist objectively, outside the head where we can examine them. The first is spoken or written language. Think of the *Encyclopedia Britannica*. An encyclopedia *represents* considerable portions of the world. Note that in the case of language, the English language in which the *Encyclopedia* is written, the relations in the world being described are not preserved as relations on the printed page. Relations in the world are represented almost entirely by *things*, that is, *words*, in the language system. The word *chair* and the word *inside* are both simply elements of language, and if you do not know English, you do not know that one is a noun

¹ This article was the presidential address delivered at the meeting of the Western Psychological Association, Anaheim, California, April 13, 1973. It was prepared with support from the National Institute of Mental Health Grant MH 20-449-02 for Studies on Spatial Representation.

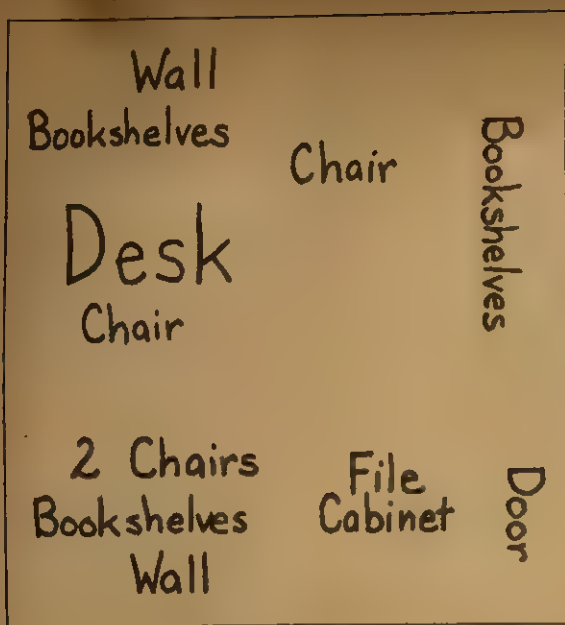

Figure 1. A hybrid (digital-analogue) representation of an office.

and the other a preposition. This substitution of things for relations is one of the most fundamental of all linguistic devices. The English language and, in fact, all other natural languages employ it quite effectively in describing large portions of what we call reality.

Another kind of representational system that we are all familiar with is the *map*. A map is quite different from language in that it is an analogue representation, whereas language is a digital representation. What this means, at least for our present purposes, is that relations among the items being mapped, items like cities, lakes, rivers, and so on, are represented by relations on the map, whereas they are not in language. In fact, in the special case of the map, space is represented by space; within certain well-understood limits, the map is just a minification of the terrain that is being mapped. It is not, of course, a completely literal minification. On the map, towns are usually represented by black circles, though they do not look like black circles from an airplane; on this microlevel the analogy is not maintained.

Digital systems of representation and analogue systems may coexist in many combinations. The *Encyclopedia Britannica* contains pictures and maps. Likewise, a map contains words to tell the names of towns, states, lakes, and rivers. Furthermore, we can have all sorts of hybrid systems, as in Figure 1, in which gross spatial relationships be-

tween objects are shown in an analogue manner—a maplike manner—but spatial relationships *within* objects are not shown. The objects are merely symbolized by arbitrary words.

Now, I think nobody would particularly object to my saying that both the map and the encyclopedia contain knowledge. Do we really want to say, though, that the *Encyclopedia Britannica* knows the various facts that it contains? I suspect you would be uncomfortable with that proposition, and, just to exacerbate your discomfort a little, let me ask you to imagine a person who knows nothing about the English language, let us say a Chinese, who is nevertheless gifted with such uncommon eidetic imagery that he can look through the encyclopedia and retain a precise visual image of every page, which he can call up at will and, given enough time, even reproduce. Are we willing to say that he *knows* what is in the *Encyclopedia Britannica*? Again, this does not seem right, and the reason it does not is that “knowing” at least connotes some kind of utility, some kind of consequences for behavior. Let us sidestep the discussion of “meaning” that suggests itself at this point and merely ask, very explicitly: Why *is* representing the world a good thing biologically—that is, for survival? It is not too hard to give a commonsense answer to this question, and I think the commonsense answer is quite right. If it is not obvious that all knowledge is important for survival, it should be at least moderately obvious that *knowing how* is biologically important. It appears to me that *knowing how* is indeed both the beginning and the end of knowledge.

The basis for *knowing how* can be represented in a somewhat oversimplified way as an SRS linkage, like this:

$$S_1, R \rightarrow S_2.$$

If situation S_1 obtains at a given time, and I do R , then situation S_2 results. If I *know* this, I know how to change situation S_1 into situation S_2 . The beginning of knowledge, I think, is to be found in the fact that we live in a lawful world, in which propositions of this SRS type have some continuing validity from one day to the next. If we did not live in a world in which lawful relationships of this form existed, learning would simply not be worthwhile to the organism at all—nor, for that matter, would innate reflexes or tropisms have any value. It is only by doing things that change one situation into a more favorable situation that the organism

can possibly affect his chances of survival by his own behavior. Likewise, the end of knowledge, that is, the utility of knowledge, lies in knowing how to change things for the better and to avoid changing them for the worse. This SRS notation is shorthand for something that is a lot more complex, of course. If we wanted to get a little more fancy in one fairly obvious way, we should formulate this in terms of a conditional probability matrix, because S_2 may not always follow S_1 and R ; it may merely be a good bet; also, S_2 may happen regardless of R , and so on. Without pursuing this probabilistic aspect, let me just point out that the organism will be better off to the degree that he can slice up the world into chunks such that situations described in terms of those chunks yield more determinate SRS relationships than if the world were partitioned otherwise. In other words, good organization in the representational system is organization that makes for relatively determinate SRS linkages; poor organization is that which makes for more indeterminate linkages.

Although I am proposing that *knowing how* is the beginning and end of knowledge, I am not proposing that it is necessarily the middle. The middle may take quite a different form. In fact, there may be considerable advantage in depersonalizing the R portion of the SRS linkage. To take one such step: The R may be, not what *I* do, but what *one* does, what some generalized person might do in that situation. Thus, if I see another person perform the act with a determinate result, I may imitate him; I may say that if he can do it, I can. There are further steps of depersonalization in which the representation can simply take the form of causal linkages between events. If I understand how the world works, if I effectively represent what Tolman and Brunswik (1935) called "the causal texture of the environment," then the opportunity exists for me to intervene in the causal network and make things come out my way.

I think the utility of knowledge has to be explained in terms such as these. But let me add that we have many items of knowledge, the utility of which we would be hard put to demonstrate individually. Accumulating knowledge, at least at the human level, is a lot like saving pieces of string, for which the classical justification is that "It may come in handy some day." So it is with knowledge.

My argument, then, is not that representation is *reducible* to SRS linkages but merely that it must

embody information from which SRS linkages can be derived conveniently when the occasion demands. Phenomenally, the set of representations we are talking about is completely identifiable with "the external world as we know it." But the scientific problem is to characterize this system in more objective terms, looking at it from the outside, that is, as a system. How can we *represent* the representational system?

There is one thing that the system is certainly *not*: It is not just a lot of stimulus objects (or surrogates thereof) tied together by simple, uniform associative bonds. Objects in the world as we know it are indeed associated, but they are associated by *particular relations*, and relations have to be differentiated one from another. Relations have quite as much fine structure as objects and classes of objects have. The situation that is described by the sentence "John gave the ball to Mary" cannot be represented by undifferentiated associative linkages between John, Mary, and ball. The particular act of giving, of exchange of possession, is involved here, and it takes a particular direction—the ball passes *from* John *to* Mary. The relations that we wish to represent vary tremendously one from another. For example, the relationship that is described by the word *give* is of a completely different *family* from the relationship that is described by the words *is a*—as in "John is a boy," or "John is a dog," as the case might be. (If I say "John is a dog," that is essentially a statement of how I can transfer knowledge. Whatever I know about dogs, I can apply to John.) If only one kind of relationship between the elements of a representational system is possible—that is, a simple associative bond—the only way such a system can be made to represent the numerous and diverse relations it has to cope with is by transforming these relations into *things*, or elements—just as they are transformed into words in natural language—in which case the associative bond will have a status comparable to that of serial order in language.

Now, should we take one further step and suppose that language *is* the representational system, for man? This position has been favored by a good many behaviorists in the past, who have supposed that anything they could comfortably call knowledge does not come into being until the human level, when language becomes available to subserve that knowledge.

It is not difficult to refute this hypothesis, at least in its most naive form. For example, Bartlett (1932) showed some years ago that memory for stories is not in terms of the words that make up the stories, but in terms of the ideas. Words, in other words, are attached to representational structures that are more fundamental than language. These structures can be given various names. We can call them concepts; we can call them logogens, as Morton (1969) did: In common parlance, they are the *ideas* to which the words are attached. We are all clearly aware that the word *tree* is not the same as a real tree—even Premack's (1970) chimpanzee Sarah knows this difference. But now let me remind you, once again, that what you know as a real tree is not the real tree out there at all, but your representation of a tree, so there has to be some level of representation that is not verbal. Furthermore, I do not believe for a moment that concepts come into being only when language is acquired. It is much more plausible to suppose that subhuman animals—certainly the higher mammals—have concepts and concept structures that are not ridiculously different from ours, and that when these concept structures reach a certain level of evolution, they are ready to have language grafted onto them. I think a comparative psychology of semantics is very much a possibility and that something of the sort is coming into being at this time, particularly with the work of people like Gardner and Gardner (1971) and Premack (1970), who are teaching language to chimpanzees. It seems moderately clear from their work that lower animals do have concepts just sitting there waiting for words to be attached to them. Premack emphasized this point and gave some evidence for it. The Gardners found that their chimpanzee Washoe would say "dog" either to a real dog or to a picture of a dog, or to the sound of a dog barking. Herrnstein and Loveland (1964) got similar results, even with pigeons. They found that pigeons would give a particular response to human figures generally and would even give the same response to parts of human beings, such as hands. So it seems by no means unreasonable to suppose that lower animals, in many cases, may have already evolved languages of their own—languages peculiar to their own nervous systems. Covert languages, or languagelike processes, may be entirely possible in the absence of language responses. Let me suggest, then, that some of the structures that

we find in natural languages may be a guide, albeit a feeble one, to the nature of languagelike processes at the logogen or concept level. One can certainly imagine that there are unitary events in the nervous system that correspond to objects, or classes of objects; that there is a "dog" neuron somewhere and a "table" neuron somewhere else. These would be essentially what Konorski (1967) suggested as *gnostic units*. But there may likewise be unitary processes, even in the case of the lower animals, that are the precursors of relational words like *inside*, *before*, *give*, and so on. Relations, like objects, may be represented in digital terms as in fact they are in language.

There are many psychological functions, however, that give every indication of entailing *analogue* representation, that is, representation in which relations are represented by relations. To take an example that is by no means the most obvious: People seem to represent numbers in an analogue fashion. Moyer and Landauer (1967) found that if a subject was asked to tell which of two numbers was greater, his reaction time was shorter the greater the difference between the two numbers. This is what you would expect from an analogue representation, but it is exactly the opposite of what you would expect if, for example, the subject were counting from one number to the other. More generally, I think that any psychophysical continuum to which metric considerations apply, that is, any continuum that is potentially scalable, is essentially an analogue system, or subsystem. The very fact that a subject is able to squeeze a hand dynamometer as hard as a light is bright (Stevens, Mack, & Stevens, 1960) is exceedingly difficult to understand at all, except in terms of analogue processes. Some people have tried to conceive psychophysical continua as the axes of a huge multidimensional space in which objects may be represented as points. I think that in general this is the wrong approach. What is more typically the case is that the psychological continuum functions as a medium for the representation of relations—a medium *in which* relations occur (see Attneave & Olson, 1971).

Perhaps the most important case of all in which analogue representation seems to be necessary is that of the system for representing physical space—the tridimensional space around us. If anything seems immediate to us, in our perception of the world, it is this space in which objects are *located* and in which we move about. The three dimen-

sions of physical space are related to one another in quite a unique way. They are *isotropic*: the same metric applies to all three. You can use a yardstick to measure the height of something, or the width, or to measure in any oblique direction you like. Moreover, a yardstick *looks* just about a yard long regardless of its distance away and the angle at which it is viewed. Physical entities are all represented as having determinate locations in this space, and this is true of imagined space as well as of perceived space. The animal *knows where* the water hole is.

Now, it is true that we have linguistic terms for spatial relationships: *above, behind, in front of, inside, outside*, and so on. It nevertheless seems exceedingly likely to me that these words refer to relations in an analogue model of space. This assumption of a tridimensional analogue model of physical space has some important theoretical advantages. For example, the Gestalt psychologists (e.g., Koffka, 1935) and Ernst Mach (1886/1959) before them argued that in perceiving objects we represent them in the simplest way that is consistent with the constraints of the input, the stimulation. This is the Gestalt principle of *Prägnanz*, and there is a great deal to recommend it. Several years ago, Robert Frost and I (Attneave, 1972; Attneave & Frost, 1969) did some experiments, and the results were quite consistent with the *Prägnanz* account of space perception. Thus, we were led to ask: What does one have to assume about the nature of a system that is capable of *finding* a simplest representation? It appeared to us that the minimum assumptions involved some kind of analogue tridimensional model in which objects *could* be represented either more or less simply and in which more complicated representations could be smoothly transformed into simple ones (i.e., by continuous, as opposed to discontinuous, processes) under the guidance of some feedback signal from a primarily digital descriptive system.

An arrangement of this sort is suggested in Figure 2. On the left, we have a tridimensional modeling medium, in which any representation consistent with the stimulus constraints *might* be constructed. This representation is *described* in the center box in Figure 2, and if it changes from one moment to the next, any resulting change in the complexity of the description is then fed back as a hot-cold signal into the tridimensional system, thereby guiding it into a *simplest* representation as

Figure 2. Outline of a system for achieving economical representations.

a stable state. This is essentially a hill-climbing machine, and the analogue medium provides a smooth terrain, so to speak, for the hill climber to operate on.

An analogue stage like this also makes a great deal of sense in terms of the identification or categorizing of objects, because the descriptive machinery is taking its descriptions, or its defining features of objects, not from the flat picture on the retina but from a model of the tridimensional world. It is describing solid objects rather than plane projections of the objects.

Evidence for the analogue modeling of physical space comes from quite diverse sources. A few years ago I became intrigued with an old study by H. H. Corbin (1942) on apparent movement, in which he found that the time interval between two flashing lights necessary to produce apparent movement varies with the distance between the lights (as Korte's third law of apparent movement says it should) but that the distance in question is not the retinal distance, not the visual angle between the lights, so much as their *physical* separation. He dissociated the two by presenting the lights on a slanting board. Gene Block and I (Attneave & Block, 1972) have recently done a series of similar experiments in which we have fairly thoroughly verified this finding. In fact, we found that the time interval necessary for apparent movement varies with the phenomenal or perceived distance between the light stimuli even when this distance is varied by purely illusory means, that is, by placing the lights at different apparent depths in a picture. What this shows, or what we believe it shows, is that apparent movement must be occurring in a tridimensional representational medium in

which the isotropy of physical dimensions is fairly well preserved.²

However, the most compelling evidence I know for the existence of a tridimensional modeling medium in the head comes from the work of Roger Shepard and his students. Shepard and Metzler (1971), in a study that many of you know, presented the subject with two pictures of tridimensional objects and asked: "Can one of these be rotated into the other? Are they the same except for orientation?" In the case of positive responses, that is, when one could be rotated into the other, the reaction time turned out to be a very precise linear function of the angular difference between the objects. Furthermore, it made no difference whether the rotation was in the frontal plane or in depth: The reaction time function was almost identical for the two types of rotation. This and other studies from Shepard's laboratory, which I do not have time to review, show beyond any reasonable doubt that when one rotates a mental image from one aspect to another, the representation of the object is in fact going through all of the intermediate aspects in a continuous manner. I have no idea how anybody could possibly account for these results without postulating an analogue representational medium.

This brings up the business of imagination and images, and I would like to suggest that this tridimensional modeling medium can be used not merely to represent the current input but also to represent images that are taken from memory, that is, that imaginary scenes can be reconstructed in space and that the organism can then proceed to use this as a work space in which he tries out things and sees what happens. He can engage in vicarious manipulation; he can engage in vicarious locomotion. He can try out the results of particular forms of behavior before he commits himself to them in practice. This highly developed facility for handling spatial information may be used in various ways. Consider, for example, the popularity of graphs, in psychology and other sciences, in

which nonspatial continua are mapped onto spatial coordinates in order to make functional relationships more easily apprehended.

Now, if images in this space can be generated from memory, the question immediately arises, In what form do they exist in memory? We might suppose, of course, that they are *stored* in an imagelike, or picturelike, form. Alternatively, we could suppose that they are stored as languagelike descriptions, which are reversible in the sense that images can be reconstructed from them. Pribram (1971) has a third alternative, or perhaps an in-between alternative: He believes that images are stored in the form of neural holograms of some sort. This is a very real possibility, but I am more inclined to favor the notion of reversible descriptions. In a remarkable article published a few years ago, the Dutch psychologist Leeuwenberg (1971) developed a powerful descriptive language in terms of which highly complex tridimensional visual forms can be represented. These descriptions are about as economical as they can be; that is, they take into account virtually all of the internal regularities of the forms being described to eliminate redundancy. Moreover, they are reversible: They can be used as instructions for rebuilding the form. Leeuwenberg believes, as I do, in the necessity of a tridimensional analogue representational medium from which such descriptions can be taken and into which images can be "projected" from descriptions.

In any case, if we suppose the existence of languagelike representational structures, the elements of which have a wordlike status, whether in memory or in consciousness, we need to consider how and where these structures get their *meaning*. How does the nervous system understand its own language? - One place to look for the meaning would certainly seem to be in the imagery that the description can generate. In other words, what has the function of a *logogen*, looked at one way, may also have the function of an *iconogen*, looked at the other. But there is another aspect of meaning that I think is even more essential. I can imagine going for a walk and encountering a dog, or a bird, or a wildcat in the woods, but how the scenario progresses beyond that point is highly dependent on *which one* of the three I imagine meeting. The rules of the game are by no means the same for dogs, wildcats, and birds; the SRS linkages that are plausible are extremely different

² I have just learned that the Japanese psychologist Jiei Ogasawara (1936) did a study of this type that antedated Corbin's by several years. His results were quite consistent with those mentioned in the text: The apparent movement threshold was highly dependent on apparent separation when viewing distance was varied with retinal separation held constant. I am grateful to Tadasu Oyama for bringing Ogasawara's article to my attention and for providing me with a copy and an English summary of it.

in the three cases. The real point or utility of identifying anything is in order to access the rules by which it interacts with other things and, more particularly, with us. We may be able to suppose that the rules of geometry, and perhaps even some very simple principles of causation, are embedded in the spatial representational medium, but a great many other rules are certainly dependent on *what* it is that is represented in that medium.

However, these two aspects of meaning that I have just suggested—that is, connection with imagery on the one hand, and access to rules on the other—are not as distinctly different as they may seem at first. I am thinking particularly of deGroot's³ work with chess masters who are able to look at some chess position from a real game for five seconds and afterwards reconstruct it perfectly. It becomes quite evident from their reports that they are not just assigning particular pieces to particular squares on the board, but rather remembering *functional relationships* between pieces—what piece is threatening another, what piece is guarding another piece against a threat, and so on. In other words, the rules of the game turn out to be quite essential to the way the position is remembered and reconstructed.

It should be obvious at this point that I do not have a beautiful, elegant, comprehensive answer to the question that I posed in the title of this presentation. But let me leave you with this suggestion. Let me ask you to imagine—use your spatial representational system to imagine—a 2×2 table. On one axis put “digital, languagelike processes” versus “analogue, maplike processes,” and on the other axis put “consciousness” versus “memory.” Now, if we can ever figure out what belongs in each of these four cells, and how each of the four is related to the other three, then I think we shall possibly know what knowing is.

Toward a Convergence in Hypnosis Research

NICHOLAS P. SPANOS *Medfield State Hospital, Medfield, Massachusetts*

THEODORE X. BARBER *Medfield Foundation, Medfield, Massachusetts*¹

Within the last two decades, methodological and theoretical controversies in the area of hypnosis research have gradually consolidated into two alternative paradigms (Chaves, 1968; Spanos, 1970; Spanos & Chaves, 1969, 1970; Tellegen, 1970). The older paradigm, which we shall call the *state* viewpoint, assumes that the hypothetical construct *hypnotic state* or *trance state* is a useful conceptual tool for organizing the available data and for generating fruitful research in this area. The alternative paradigm, which we shall call the *nonstate* viewpoint, rejects this assumption and argues that the data can be more parsimoniously conceptualized in terms of constructs that are already an integral part of contemporary social psychology.

The research generated by each of these alternative paradigms has spawned a number of useful developments. A wealth of new information has been compiled concerning the antecedents and correlates of response to hypnotic suggestions (Fromm & Shor, 1972; Gordon, 1967; Moss, 1965).² Also,

new methods have been developed for studying the hypnotic subject's experiences, and numerous theoretical issues have been recast in operational terms and, thereby, have been brought into sharper focus (Coe, 1973).

Inevitably, the proponents of a particular scientific paradigm tend to stress the differences rather than the similarities between their conceptualization and the alternative point of view. The tendency of investigators to maximize such differences is understandable. Furthermore, it appears to be useful. It forces the investigator to search for and continually examine implicit assumptions underlying his own paradigm and the rival paradigm that might otherwise remain unrecognized. Unfortunately, the tendency to stress differences rather than similarities between paradigms may also engender a number of negative consequences. First, it may lead investigators into self-righteous polemics which are of little value in advancing knowledge. Second, and more important, it may obscure significant areas of agreement between proponents of alternative paradigms and thereby foster a distorted view of the research area as a whole.

We believe that the theoretical controversies in this area have overshadowed a significant degree of agreement concerning the factors that mediate response to hypnotic suggestions. More specifically, we believe that major theoreticians in the area of hypnosis, regardless of paradigm affiliation, are converging on the conclusion that responding to suggestions involves at least two interrelated factors. The first can be conceptualized as a willingness on the part of the subject to cooperate with the experimenter in fulfilling the aims of the suggestions. The second can be described as a shift in cognitive orientation from an objective or pragmatic perspective to one of involvement in suggestion-related imaginings. The construct *involvement in suggestion-related imaginings* encompasses at least two simultaneously occurring cogni-

² Although hypnotic behavior is multifaceted (Barber & Calverley, 1969b), its most important and most thoroughly studied component consists of responses to "hypnotic suggestions." Hypnotic suggestions can be subdivided into two sets: (a) suggestions that constitute the "hypnotic induction procedure" (typically consisting of repeated suggestions that the subject is becoming relaxed, drowsy, sleepy, and is entering a hypnotic state) and (b) suggestions that typically are given after the hypnotic induction procedure, such as suggestions for hand levitation, arm rigidity, analgesia, hallucination, age regression, amnesia, posthypnotic behavior, etc. Since we shall be discussing primarily the factors that determine responsiveness to suggestions, we should emphasize at the outset that theories of hypnosis have been primarily theories of responsiveness to suggestions; that is, they have been concerned primarily with explaining responsiveness to the two sets of hypnotic suggestions described above.

tive processes: (a) sustaining and elaborating imaginings that are consistent with the aims of the suggestions and (b) disregarding information that is inconsistent with the aims of the suggestions. These two cognitive processes are not separate or independent; instead, they are two sides of one unitary psychological process. An individual cannot sustain and elaborate a pattern of imaginings while also focusing on information that contradicts his imaginings. On the contrary, the process of sustaining imaginings necessarily implies the complementary process of ignoring or disregarding inconsistent and irrelevant information.

In this article we shall examine the theoretical formulations proffered by major proponents of the two alternative paradigms with an eye toward delineating the areas of conceptual agreement. We shall also examine the empirical evidence to see whether it supports these areas of agreement.

Willingness to Cooperate in Fulfilling the Aims of the Suggestions

This section is divided into two parts. The first part shows that major investigators in this area, regardless of their paradigm affiliation, appear to be in basic agreement concerning the importance of the subject's motivations and attitudes in determining response to hypnotic suggestions. The second part of the section summarizes the empirical evidence that relates to this point.

THEORETICAL FORMULATIONS

It appears that major investigators, regardless of theoretical orientation, agree that hypnotic behavior is motivated or goal directed and that the good hypnotic subject is an individual who construes the hypnotic situation as one in which he is willing to cooperate in fulfilling the aims of the suggestions. This point was made succinctly by White (1941), who contended that hypnotic behavior involves "meaningful, goal-directed striving, its most general goal being to behave like a hypnotized person as this is continuously defined by the operator and understood by the subject [p. 503]." Along similar lines, Gill and Brenman (1959) asserted that the hypnotist is successful only when he converts the subject "into a person whose major overt characteristic is his willingness, indeed his eagerness, to see, hear, think, and do what he is told to by the hypnotist [p. 10]."

Although many, if not all, investigators appear to recognize the importance of motivation for hypnotic performance, there is little agreement concerning the factors that produce favorable motivation. For example, psychoanalytically oriented writers view the motivation for hypnotic performance as deriving from dependency and from masochistic and erotic needs (Ferenczi, 1950; Freud, 1953; Kubie & Margolin, 1944; Schilder, 1956). For example, Ferenczi (1950) suggested that the motivating force behind hypnotic performance stemmed from the reactivation of the Oedipus complex, with the hypnotist and subject standing in a parent-child relationship to one another. More recently, Shor (1962, 1970) advanced a related thesis. He suggested that hypnotic responding involves three separate psychological processes. One of these, which he labeled *depth of archaic involvement*, derives from the intense needs of some subjects to cooperate with and please the hypnotist. As Shor (1962) pointed out, the notion of archaic involvement has much in common with psychoanalytic formulations of hypnosis that attribute the motivational basis of hypnotic performance to a "transference" relationship which purportedly develops between the hypnotist and the subject (cf. Gill & Brenman, 1959).

Investigators who do not accept psychoanalytic theories have also emphasized the importance of motivation in hypnotic performance, but they differ from the psychoanalytic writers in that they stress the situational sources of the subject's motivation. Both state theorists (Orne, 1959, 1966; Pattie, 1956) and nonstate theorists (Barber, 1961; Meeker & Barber, 1971; Sarbin & Coe, 1972) have noted the strong social demands for conformity inherent in the hypnotic situation. Sarbin and Coe (1972) indicated that the degree to which the subject enacts hypnotic behavior will, in part, be determined by his expectations of what the hypnotic role involves and by the extent of his self-role congruence. Extent of self-role congruence is a motivational construct referring to the degree to which the subject views the components of the hypnotic role as congruent with and acceptable to his conception of himself. Barber (1969, 1970a) has stressed heavily the role of motivational variables in hypnotic performance and has presented an extensive series of experimental studies indicating that individual differences in hypnotic performance are due, in part, to differences among subjects in their attitudes, motivations, and expectancies toward the hypnotic situation. In brief, despite differences in

pinpointing the factors that produce favorable motivation, one theoretical generalization that cuts across the state and nonstate paradigms may be stated as follows: The subject's willingness to cooperate in carrying out the aims of the suggestions is an important precondition for hypnotic performance. Let us now summarize the empirical research that supports this generalization.

EMPIRICAL DATA

As we pointed out earlier in this article, psychoanalytically based formulations of hypnosis usually stress the importance of long-standing, transsituational need dispositions as the motivating force behind hypnotic responsiveness. This line of thought has led numerous investigators to search for correlations between responsiveness to hypnotic suggestions (hypnotic suggestibility) and generalized motivational dispositions such as dependency, masochistic needs, need for affiliation, and the like. This research, which has been reviewed elsewhere (Barber, 1964), has yielded either negative or inconsistent results. The available data fail to support the notion of a relationship between hypnotic suggestibility and generalized, transsituational motivational dispositions.

Attempts to relate situational-specific attitudes and motives to hypnotic suggestibility have attained a greater degree of success. Investigators who differ in theoretical persuasion have consistently reported that positive attitudes or motivations toward the hypnotic situation are correlated with hypnotic suggestibility (Andersen, 1963; Barber & Calverley, 1966; Coe, 1964; Coe & Sarbin, 1966; Diamond, Gregory, Lenney, Steadman, & Talone, 1972; J. R. Hilgard, 1970; London, Cooper, & Johnson, 1962; Meleis & Hilgard, 1964; Shor, Orne, & O'Connell, 1966).²

Studies that experimentally manipulated the subjects' attitudes and motives toward responding to suggestions achieved results that are congruent with

the correlational studies cited above. For example, a series of studies summarized by Barber (1969, 1970a) indicated that subjects given brief instructions aimed at enhancing their motivation to perform well exhibit a level of suggestibility that is (a) higher than that achieved by control subjects (who are not given motivational instructions) and (b) about as high as the level achieved by subjects who have been exposed to a standardized hypnotic induction procedure that focuses on repeated suggestions of relaxation, drowsiness, and sleep. Several studies (Barber & Calverley, 1964a, 1964b; Cronin, Spanos, & Barber, 1971; Diamond, 1972; Kinney, 1969; Spanos & McPeake, 1973b) have also shown that the inculcation of positive attitudes and motivations can enhance hypnotic suggestibility, while the inculcation of negative attitudes and motivations can adversely affect suggestibility.

Taken together, the studies cited above indicate that subjects who view hypnosis as positive and worthwhile and who look forward to participating and cooperating are more likely to respond to hypnotic suggestions than subjects who view the hypnotic situation from a negative perspective. However, these studies also indicate that a substantial proportion of subjects with positive attitudes and a willingness to cooperate do not exhibit high levels of hypnotic suggestibility. These empirical results support a generalization that cuts across the state versus nonstate paradigms: A willingness to cooperate constitutes an important but not sufficient condition for hypnotic performance.

Involvement in Suggestion-Related Imagining

All theorists appear to agree that extramotivational factors need to be postulated in order to attain a comprehensive account of hypnotic performance. White (1941), for example, argued that hypnotic behavior will be manifested only when goal-directed strivings occur in the context of other psychological processes which he subsumed under the rubric of an *altered state of consciousness*. Gill and Brenman (1959) indicated that the subject's willingness to cooperate merely sets the stage for the occurrence of other psychological processes which they conceptualized in terms of the development of a regressed, quasi-stable ego subsystem that mediates hypnotic performance. Orne (1959, 1966, 1971) emphasized that a high level of motivation by itself cannot account for the subjective aspects of hypnotic performance. As pointed out above, Shor

² Similar findings have also been obtained with respect to subjects' expectations concerning their hypnotic performance. Subjects who expect to respond well to hypnotic suggestions exhibit higher levels of responsiveness than subjects who do not expect to respond well (Barber & Calverley, 1966, 1969b; Dermen & London, 1965; Gregory & Diamond, 1971; Meleis & Hilgard, 1964; Shor, 1971; Unestahl, 1969). Although, from our viewpoint, expectancies play an important role in hypnotic responsiveness, this factor has not been emphasized by state and nonstate theorists to the same extent as attitudes and motivations, and thus we are not giving it primary emphasis here.

(1962, 1970) argued that appropriate motivation is only one of three factors that are necessary for hypnotic performance.

The nonstate theorists have also rejected a purely motivational theory. Sarbin and Coe (1972) stressed that hypnotic performance requires a set of imaginative skills within an appropriate motivational context. Similarly, Barber (1970b) and Barber, Spanos, and Chaves (in press) presented data indicating that, in addition to possessing positive motivations, attitudes, and expectancies, good hypnotic subjects think and imagine with those things that are suggested and, in fact, become "involved" in imagining.

The extramotivational factors have been variously conceptualized as *trance*, *altered state of consciousness*, *regressed ego subsystem*, *role-relevant skills*, *thinking and imagining with the suggestions*, and *imaginative involvement*. These varied conceptualizations have been defined and operationally delineated with different degrees of precision. However, all of these formulations share in the belief that constructs other than positive motivation or cooperation must be employed if hypnotic behavior is to be explained.

A very important consideration here is that, despite the use of different terminologies, there appears to be substantial agreement among theorists concerning the nature of the extramotivational factors that mediate hypnotic behavior. Both state and nonstate theorists appear to be converging on the conclusion that responsiveness to hypnotic suggestions involves a shift in set or orientation away from the pragmatic one that governs our everyday transactions to one that involves imagining. This shift in orientation appears to involve at least two interrelated components: (a) a tendency to carry out and also to elaborate imaginings consistent with the suggestions that are administered, together with (b) a tendency to simultaneously ignore or reinterpret information that contradicts the imaginings. We shall first present evidence indicating that both state and nonstate theorists are converging on this conclusion, and then we shall summarize the empirical work that supports it.

THEORETICAL FORMULATIONS

The importance of suggestion-related imaginings and the disregarding of contradictory information have been recognized and afforded a central position in the theoretical formulations of nonstate theorists. Sarbin (1950), for example, viewed the good hyp-

notic subject's ability to carry out suggestion-related imagining while simultaneously disregarding inconsistent information as a role-relevant skill. In a classic paper (Sarbin, 1950) that influenced the formulations of both state and nonstate theorists, he argued that adoption of the hypnotic role involves a shift in perspective from an alert, objective frame of reference to a relatively uncritical acceptance of what the hypnotist says. More recently, Sarbin and Coe (1972) reiterated and expanded this position. They contended that, when the good hypnotic subject is responding to suggestions, he is not concerned about evaluating the veridicality of the imaginative experiences generated by the suggestions. Instead, the good subject is actively imagining those things that are suggested and such active imagining precludes the possibility of simultaneously focusing on information that is inconsistent with the suggestions.

Sarbin and his associates (Sarbin, 1950; Sarbin & Coe, 1972; Sarbin & Juhasz, 1970) have been particularly concerned with delineating the concept of imagining. They have criticized earlier conceptualizations that viewed imaginings as *conditioned sensations* or as quasi-perceptual *pictures in the mind*. As an alternative, they have suggested that imaginings can be more fruitfully conceptualized as active, albeit covert, behavioral processes more akin to creative play acting or muted role taking than to a passive "looking at" quasi-objects in a hypothetical mind-space. For these investigators, imaginative activity involves a large component of "as if" behavior. When an individual is imagining, he is, to some extent, acting as if certain hypothetical events are, in fact, occurring. These investigators have argued that imagining can be usefully conceptualized as falling along a dimension of involvement where the degree of involvement refers to the intensity with which the process is carried out. Sarbin and Coe (1972) further pointed out that the tendency to become involved in imaginings can be conceptualized as a skill or ability possessed by individuals to different degrees. Successful enactment of the hypnotic role calls for one aspect of this skill, namely, the ability to become involved in imaginings that are generated by verbal suggestions.

Barber and his associates (Barber, 1970b; Barber & DeMoor, 1972; Barber & Ham, 1974; Barber, Spanos, & Chaves, in press) have stressed the role of "thinking and imagining with the suggestions" as a mediator of response to suggestions given in hypnotic situations and also in nonhypnotic situa-

tions. Barber (1970b) pointed out that responding to suggestions involves a shift in set that is analogous to the shift that occurs when a person becomes involved in watching a movie or reading a novel. He views the subject who is responsive to suggestions as actively imagining the themes that are suggested while simultaneously failing to attend to contradictory information. Thus, Barber and DeMoor (1972) stated:

When the suggestibility-enhancing factors have given rise to positive attitudes, motivations, and expectancies, the subject is ready to think with and vividly imagine those things that are suggested. The more a subject thinks with and vividly imagines the suggested effects, the less he tells himself that the suggested events cannot or will not occur, that is, the less he covertly contradicts the suggestions. We see responsiveness to test-suggestions as directly related to thinking with and vividly imagining those things that are suggested and inversely related to thinking against (covertly contradicting) the suggestions [pp. 123-124].

Barber and his associates (Barber, 1970b; Barber & Ham, 1974; Barber, Spanos, & Chaves, in press) applied the concept of *thinking and imagining with those things that are suggested* to a wide variety of hypnotic behaviors such as suggested age regression, hallucination, analgesia, and amnesia. This viewpoint has been further developed by Spanos (1971, 1973), who has delineated one aspect of the process of thinking and imagining with the suggestions that is labeled *goal-directed fantasy*. Goal-directed fantasy involves imagining a situation that, if it actually occurred, would tend to produce the behavior called for by the suggestion. For example, a subject who was administered an arm levitation suggestion would be engaging in goal-directed fantasy if he imagined a pulley, a helium-filled balloon, or a magnet raising his arm. Spanos (1973) indicated that "good" subjects pass suggestions when they become highly involved in their goal-directed fantasies and, thereby, temporarily fail to evaluate the veridicality of their suggested experiences. On the other hand, "poor" subjects are either unwilling or unable to become involved in goal-directed fantasy. Instead, they continually evaluate and thereby contradict the veridicality of the suggestions.

A number of major theorists who adhere to the state paradigm (e.g., Arnold, Shor, Hilgard, and Gill) also view the cognitive processes subsumed under the rubric of *involved imaginings* as important in explaining hypnotic behavior. Let us look at the formulations of each of these investigators in turn.

Among earlier state theorists, Magda Arnold (1946) was the most explicit in pinpointing the

importance of *intense imagining* and the interrelated process of inattention to contradictory information. For example, she wrote:

Hypnosis essentially consists in concentrating and therefore intensifying the subject's imaginative processes. Directed toward one focus, the situation described by the experimenter, the subject will be able to imagine this situation much more intensely than he is able to do ordinarily, without the usual internal and external distractions If the hypnotized subject is told that his arm is stiff and he will not be able to bend it, he immediately conceives of his arm as being stiff, and no contradictory thought will interfere. As long as the arm is imagined as stiff the arm *feels* stiff, and with this feeling comes an actual contraction of muscles; thus, as long as this feeling of rigidity lasts, the arm really cannot be moved [p. 116].

Arnold (1946) also provided a description of the processes occurring in the subject who does not become hypnotized. Her description emphasized the unwillingness or inability of the nonhypnotized subject to "lay aside" irrelevant thoughts and to allow himself to imagine those things that are suggested.

More recent attempts to conceptualize hypnotic experiences within the context of the state paradigm have been made by Shor (1959, 1962, 1970). In his latest theoretical paper, Shor (1970) compared the good hypnotic subject to an individual who becomes highly involved in reading a novel. When an individual is in hypnosis and also when he is absorbed in reading a novel, he employs information from an external source to generate and elaborate imaginings that temporarily become the main focus of his attention. Shor also recognized the importance of the subject's ignoring information that contradicts his imaginings. He contended that the individual's usual transactions with the environment are guided by a set of rules or implicit assumptions about the world that constitute a framework for categorizing and interpreting ongoing experience. This framework, which Shor labeled *the generalized reality orientation*, allows the individual to develop a stable, consistent, and socially shared picture of reality. Shor went on to argue that at various times the generalized reality orientation may fade into the background of awareness and, thereby, become relatively nonfunctional. Thus, for Shor, hypnosis is conceptualized as sustained imaginings that occur at a time when the generalized reality orientation has faded into the background of awareness.

The theoretical formulations proffered by Ernest R. Hilgard (1965) and Josephine R. Hilgard (1970) have much in common with Shor's thinking. Two interrelated themes recur throughout the writ-

ings of the Hilgards and are particularly prominent in the work of J. R. Hilgard. The first theme is that the good hypnotic subject is especially capable of carrying out a pattern of fantasy that is initiated by some external source such as by a movie, by music, or by the hypnotist's suggestions. The second theme is that the good hypnotic subject becomes involved in his imaginative or fantasy productions. One component of involved imagining is inattention to both external information and also internal information (i.e., thoughts) that are inconsistent with the imaginings. Thus, J. R. Hilgard (1970) wrote:

To the extent that absorption in an activity has resulted in attention to it, some selective inattention must also be involved. It might be argued, therefore, that a subject who is able through imaginative attention to reinstate vivid experiences from the past must be setting aside other stimuli that claim his attention from the real world about him [p. 86].

In line with Sarbin (1950), J. R. Hilgard (1970) delineated a number of characteristics held in common by the good hypnotic subject and the dramatic actor. She wrote that in the case of both the dramatic actor and the good hypnotic subject:

1. There is a temporary departure from reality orientation, to the creation of an *as if* reality. 2. The actor [in the same way as the good hypnotic subject] is not merely passive but actively receptive to the demands of the role; he is involved in it and works at it. . . . The absorption is intense, interest is concentrated and empathic, so that emotions are stirred up [p. 53].

The above quotation indicates that J. R. Hilgard, in a way similar to Shor and the nonstate theorists such as Sarbin and Barber, considers two interrelated cognitive processes—suggestion-related active imagining and inattention to information that is inconsistent with the imaginings—to be central to an understanding of response to hypnotic suggestions. Other state theorists have made reference to these two processes but have not spelled out their implications for hypnotic responsiveness as precisely as Arnold, Shor, or J. R. Hilgard. White (1941), for example, suggested, but did not fully develop, the notion that hypnotic responsiveness involves a shift away from the alert frame of reference that the individual uses to sustain his conception of reality. According to White, the poor hypnotic subject is unable or unwilling to give up this frame of reference, and, consequently, he is continually engaged in contradicting the reality of the suggestions he is given.

The simultaneous processes of sustained imagining and inattention to contradictory information are

usually implied rather than directly described in psychoanalytic formulations of hypnotic behavior. Thus, psychoanalytic investigators (Gill, 1972; Gill & Brenman, 1961; Kubie, 1972; Kubie & Margolin, 1944) indicate that the induction of hypnosis involves a temporary holding in abeyance of the subject's usual reality orientation, a partial dissolution of the sense of self, and a subsequent tendency to treat the hypnotist's suggestions as if they were veridical descriptions. Recently, Gill (1972) stated that the notions of regression in the service of the ego and development of an ego subsystem, which he used earlier to explain hypnotic behavior (Gill & Brenman, 1959) are consistent with and, in fact, incorporate what J. R. Hilgard (1970) means by involved imagining.

The above discussion indicates that the cognitive processes posited by many of the major nonstate and state theorists have much in common. Investigators operating from both paradigms have stated or implied that subjects respond overtly and experientially to suggestions when they engage in involved, suggestion-related imagining. Such involved imagining is present when the subjects carry out, sustain, and, at times, elaborate on imaginings that are consistent with the aims of the suggestions, while concurrently failing to attend to or acknowledge information that contradicts the suggested effects.

Despite the foregoing important commonalities, the formulations of nonstate and state theorists contain a major difference: The two viewpoints differ in the way they view the relationship between the construct involved suggestion-related imagining and the construct hypnotic state or trance state. The nonstate theorists have rejected the utility of the notion of hypnotic state or trance state. For the nonstate investigators such as Sarbin and Barber, involved suggestion-related imagining (or its synonyms such as thinking and imagining with the themes of the suggestions) functions as an *alternative* to the traditional trance state formulation of hypnotic behavior. These investigators have replaced the trance state notion with what they believe is a more parsimonious and theoretically useful construct.

The state theorists, on the other hand, usually fail to clarify the relationship between these constructs. It is not always clear from their writings whether the construct hypnotic state or trance state is (a) a synonym for the construct involved suggestion-related imagining, (b) an antecedent condition that must exist before involved imagining can

occur, or (c) a superordinate construct that includes involved imagining together with other unspecified processes. Ambiguities of this kind have made it difficult to interpret the formulations of some of the state theorists. J. R. Hilgard, for example, has clearly stated that individuals who become involved in imagining outside of the hypnotic situation, such as when reading a novel or when listening to music, tend to be good hypnotic subjects. She has strongly implied, but never stated explicitly, that good hypnotic subjects are those individuals who become involved in their suggestion-related imaginings during the hypnotic session. At various points in her book she also uses terms such as *hypnotised*, *under hypnosis*, and *deeper hypnosis* when referring to the psychological processes occurring in good hypnotic subjects. At no point, however, does she deal clearly with the relationship between terms such as *imaginative involvement* and *hypnosis* or *hypnotic state*. Thus, it is not clear from her writings whether the "hypnotized" subject is to be considered as an individual who (a) is simply involved in imaginings that are related to the suggestions he is given or (b) is involved in his imaginings and, in addition, is in a special state (hypnosis) the characteristics of which remain unspecified.

We believe that many of the problems in this area could be overcome if all state theorists, including those who have not yet utilized a construct like involved imagining in their formulations, would attempt to specify clearly what they mean by hypnotic state or trance and how they see the relationship between this construct and the construct of involved imagining. If state theorists mean to say that the "hypnotized" subject is involved in his imaginings and is also in a special state (hypnosis) which has special characteristics that are over and above involved imagining, then they should clearly specify the nature of these special characteristics. On the other hand, if state theorists see the construct hypnotic state or trance as synonymous with the construct involved imagining, then much confusion would be avoided if they simply used the construct involved imagining and dropped the construct hypnotic state or trance which has many misleading implications that have accumulated during the past 200 years. As we have noted elsewhere (Barber, 1970b), if the construct hypnotic trance is now to be used synonymously with such constructs as involved imagining, then this

will change the meaning of the term "hypnotic trance"; the term will no longer refer to a special state basically

different from ordinary states of consciousness Since the construct "hypnotic trance" (or "hypnosis" or "hypnotic state") has always referred to some kind of basic, qualitative change in the organism and has accreted many associated connotations (including connotations of somnambulism or sleepwalking) attempts to give it a new meaning and new connotations will lead to confusion rather than clarity . . . [p. 65].

We will return to the state and nonstate paradigms in the concluding section of this article. Before we do so, however, let us summarize the empirical evidence which shows that involvement in suggestion-related imagining is closely related to hypnotic performance.

EMPIRICAL DATA

Attempts to assess the role of involved imagining in hypnotic performance have followed three general research approaches. The first approach assesses the degree to which individuals become involved in their imaginings outside of the hypnotic situation, for instance, while reading a novel, and then correlates these measures of involvement with hypnotic suggestibility. The second approach compares the responsiveness to suggestions of subjects who have been provided with a strategy for becoming involved in imagining with the responsiveness of subjects who have not been provided with such a strategy. Finally, the third approach assesses the degree of involvement in imagining displayed by good and poor subjects when they are exposed to suggestions. We shall discuss the research pertaining to each of these approaches in turn.

Nonhypnotic involvements and hypnotic suggestibility. A number of specific strategies have been used to assess the degree of involvement in imaginings that occur outside of the hypnotic situation. These strategies include (a) the use of self-report scales that assess the extent to which the subject feels that he becomes involved in such activities as daydreaming, watching a movie, reading a novel, and the like (As, 1962; Barber & Glass, 1962; Shor, Orne, & O'Connell, 1962); (b) semistructured interviews aimed at assessing the subject's degree of involvement in everyday imaginative activities (J. R. Hilgard, 1970); and (c) performance measures, such as skill in dramatic acting, that are believed to reflect degrees of imaginative involvement (Coe & Sarbin, 1966). With one exception (Barber & Calverley, 1964c), all studies in this area found a positive correlation between these various indexes of imaginative involvement and hypnotic suggestibility (Andersen, 1963; As,

1962; As, O'Hara, & Munger, 1962; Atkinson, 1971; Barber & Glass, 1962; Coe, 1964; Coe & Sarbin, 1966; J. R. Hilgard, 1970; Lee-Teng, 1965; Sarbin & Lim, 1963; Shor, Orne, & O'Connell, 1962; Spanos & McPeake, 1973a; Tellegen & Atkinson, in press). These positive results are especially impressive when it is kept in mind that imaginative involvement is the only "personality measure" that has consistently yielded positive correlations with hypnotic suggestibility.

Provision of strategies for imagining. A number of reports (Barber, Spanos, & Chaves, in press; Spanos, 1971, 1973; Spanos & Barber, 1972; Spanos, DeMoor, & Barber, 1973) have pointed out that suggestions differ in the degree that they specify a pattern of imagining or strategy which the subject can use to help him in experiencing the suggested effects. Some suggestions are highly explicit in specifying a helpful imaginary situation whereas others simply indicate the subjective effects to be experienced without providing a strategy that can help to produce them. For instance, suggestions of anesthesia of a hand that instruct the subject to imagine Novocain being injected into the hand provide an imaginative strategy for experiencing anesthesia, whereas suggestions that simply state that the hand is becoming insensitive do not provide a strategy. A number of studies have either assessed or manipulated the extent to which a strategy for imagining is provided by various types of suggestions, for example, suggestions for arm levitation, analgesia, catalepsy, and hallucination (Barber & Calverley, 1969a; Barber & Hahn, 1962; Chaves & Barber, in press; Coe, Allan, Krug, & Wurzman, 1972; Evans & Paul, 1970; Johnson, 1973; Spanos & Barber, 1972; Spanos, Barber, & Lang, in press). The results of these studies can be summarized as follows: Suggestions that provide the subject with an explicit strategy for imagining—that ask him to direct his imagining along specific channels that are congruent with the aims of the suggestions—are more likely to be experienced than suggestions that do not provide such a strategy.

The findings of another series of studies (Comins, Fullam, & Barber, 1973; Diamond, 1972; Sachs, 1969, 1971; Sachs & Anderson, 1967) indicate that suggestibility can be enhanced by training subjects to become involved in suggestion-related imaginings. The training procedures included (a) teaching subjects through the use of modeling procedures and direct instructions to carry out imaginings consistent with the subjective experiences

implied by the suggestions and (b) teaching them to exclude competing thoughts and competing sensory input from the focus of their attention. For example, Diamond (1972) assessed the effects of having prospective hypnotic subjects watch a model undergo hypnosis. He found that the best results were obtained when the model not only performed the overt behaviors that were suggested but also described in detail how and what he was imagining while he was responding to the suggestions.

Imaginative involvement while responding to suggestions. A series of recent studies assessed the relation between the degree of imaginative involvement generated by a suggestion and the extent to which the suggested effects were experienced. Spanos (1971) presented data indicating the subjects who failed suggestions for arm levitation, limb rigidity, selective amnesia, etc., were unable to sustain involvement in goal-directed imagining. In a related study (Spanos, 1973), positive correlations were obtained between the extent that the subjects reported involvement in their suggestion-related imaginings and (a) the likelihood that they would pass the suggestion, (b) the extent that they experienced their response to the suggestion as occurring involuntarily, (c) the extent that their imaginings were experienced as real events, and (d) the likelihood that they would respond successfully to more difficult suggestions.

Congruent findings have been reported by Spanos, Ham, and Barber (1973). These investigators administered a suggestion for visual hallucination to 74 subjects who had been exposed either to task motivational instructions or to a hypnotic induction procedure. The one task-motivated subject and the two hypnotic subjects who stated that they saw the suggested object and that they believed, for a few moments, that it was real, also reported sustained imagining with a concomitant failure to attend to contradictory information.

In brief, studies assessing individual differences in imaginative involvement generated by test suggestions have consistently found a positive relationship between the degree of such involvement and responsiveness to suggestions. Of course, it is important to keep in mind that these studies are primarily correlational in nature, and, therefore, causal relationships cannot be justifiably inferred from their results. Nonetheless, the results are consistent with the hypothesis that responsiveness to suggestions is, in part, a function of degree of involvement in suggestion-related imaginings.

Implications

This article has attempted to highlight the existence of significant areas of theoretical convergence that transcend the state and nonstate paradigms in hypnosis research. Specifically, many important contemporary investigators in this area seem to agree with the following generalizations: (a) The subjects' willingness to cooperate in carrying out the aims of the suggestions is an important but not a sufficient condition for a high level of hypnotic responsiveness. (b) Subjects respond overtly and experientially to suggestions when they become involved in imaginings that are consistent with the aims of the suggestions. These generalizations were shown to be supported by empirical studies carried out by investigators differing in theoretical orientation. At this point it is appropriate to consider the ramifications of the aforementioned theoretical convergence for the state versus nonstate controversy in hypnosis research.

Historically, the notion of a hypnotic state or trance developed on the basis of several superficial and misleading similarities between the behavior of mesmerized subjects and the behavior of sleeping individuals and sleepwalkers (Barber, 1973). As E. R. Hilgard (1969) noted, even today, "Hypnosis is commonly considered to be a 'state' perhaps resembling the state in which the sleepwalker finds himself, hence the term 'somnambulist' as applied to the deeply hypnotized person [p. 71]." The quasi-physiological notion of hypnotic state or trance gained theoretical ascendancy at a time when purely psychological theories were too primitive to encompass the complexities of hypnotic behavior, and when the prevailing "magnetic" theory of these phenomena was being increasingly challenged by the gains in knowledge made by nineteenth-century science (cf. Ellenberger, 1970; Sarbin, 1962). At that time, the notion of trance also became associated with highly exaggerated claims concerning the wondrous "feats" attributed to mesmerized subjects.

The nonstate view of hypnotic behavior grew gradually out of a movement aimed at curtailing the excessive claims made by some state theorists. This viewpoint became associated first with the notion that hypnotic behaviors did not involve highly unusual or transcendent phenomena and, second, with the notion that it was unnecessary and misleading to posit a special or qualitatively different state in order to explain the experiences of the good hypnotic subject.

At the present time there appears to be relatively little disagreement between state and nonstate theorists concerning the characteristics and limits of hypnotic behavior. For example, no contemporary theorist in hypnosis research argues for the existence of a unique relationship between hypnotic phenomena and sleep (Evans, 1972). Many present-day state theorists (e.g., Orne, 1971, 1972; E. R. Hilgard, 1965) are almost as critical of exaggerated claims concerning transcendent hypnotic phenomena as are nonstate theorists (e.g., Barber, 1969, 1970a; Barber & Ham, 1974; Sarbin & Coe, 1972; Sarbin & Slagle, 1972). Also, all contemporary nonstate theorists agree with state theorists that hypnotic phenomena involve genuine changes in the subject's experience that cannot be explained away in terms of faking or sham behavior (Barber, 1970b; Sarbin & Coe, 1972; Spanos, 1971, 1973; Spanos, Ham, & Barber, 1973). As we have seen in this article, there are state and nonstate theorists who seem to be converging in their conceptualizations of the cognitive processes that mediate hypnotic performance. These similarities lead to the following question: What are the important differences at the present time between state and nonstate theorists? We believe that the differences that now exist are primarily differences in approach to the subject matter and in the kinds of research questions that are pursued.

The construct trance or hypnotic state, despite its inherent vagueness and lack of amenability to operational definition, continues to dominate state conceptualizations of hypnosis. This construct seems to refer to a state that differs, not simply quantitatively, but in some basic, qualitative way, from waking states and from states of sleep. As Bowers (1966) noted, "Most [present-day] investigators interested in hypnosis believe that there is an hypnotic state which fundamentally differs from the waking state [p. 42]." This belief makes it much more likely that it will be state theorists who will conduct studies aimed at establishing a physiological basis for the hypothesized fundamental alteration. The state theorists are also more likely than the nonstate theorists to pursue research that might indicate that hypnotic performance involves unique or highly unusual changes in perceptual functioning or in cognitive functioning, such as trance logic (Orne, 1959). Although studies of this type have generally produced negative or inconclusive findings (Barber, 1969, 1970a, 1973; Barber & Ham, 1974; Hilgard, 1972; Johnson, 1972; Johnson, Maher, & Barber, 1972; Sarbin & Slagle,

1972), they have on occasion yielded some provocative results (Graham, 1969).

On the other hand, the guiding assumption of the nonstate theorists—that the good hypnotic subject is not fundamentally different from the normal individual who is cooperating in a social situation in which he is asked to experience suggested effects—will lead these investigators to continue their studies of situational and social-psychological antecedents of hypnotic performance. The nonstate investigators may be expected to probe further into the effects of such variables as how the situation is defined to the subject, what attempts are made to remove fears and misconception, and how the suggestions are worded (Barber & DeMoor, 1972; Spanos, 1973). The basic assumption of the nonstate theorists will also continue to influence their conceptualization of hypnotic performance as a set of socially influenced cognitive skills or abilities. However, despite these differences in the research proclivities of state and nonstate investigators, theoretical convergences of the type outlined in this article indicate that a good deal of the future research carried out by proponents of both paradigms will dovetail in focusing on the role of imaginative processes in hypnotic performance.

The sympathies of the present authors are, of course, associated with the nonstate paradigm. We believe that this approach offers the most useful way of conceptualizing hypnotic phenomena. Nonetheless, there is a great deal about hypnotic phenomena that remains to be learned. Diversified theoretical and methodological approaches in this area can help to generate research that will eventually lead to a more comprehensive understanding.

Two Dimensions of Tests

Psychometric and Edumetric

RONALD P. CARVER *American Institutes for Research, Washington, D.C.*¹

A recent development in testing involves the design and construction of criterion-referenced tests. *Criterion-referenced tests* are designed "to yield measurements that are directly interpretable in terms of specified performance standards [Glaser & Nitko, 1971, p. 653]." Traditionally developed tests, that is, those designed to measure a person in relation to a normative group, have been labeled *norm-referenced tests* (see Popham, 1971). The distinction between the new criterion-referenced test and the traditional norm-referenced test is important. However, the distinction is also misleading. It suggests that a newly developed test must be either norm referenced or criterion referenced in mutually exclusive fashion. This is misleading because a criterion-referenced test may be referenced to a normative group, and a norm-referenced test, to a criterion.

Not only is there a semantic problem underlying the new movement in testing but there is a substantive problem as well. The problem revolves around the measurement of individual differences versus the measurement of amount learned. Cronbach (1971) pointed out that "the testing movement in psychology started with the Darwinian emphasis on differences among individuals, and all theoretical work behind test scores has attempted to conceptualize differences in abilities or traits [p. 446]." McClelland (1973) argued, quite properly, that schools should be testing for competence rather than for ability. In other words, schools should use criterion-referenced tests rather than norm-referenced tests. McClelland appears to have generalized beyond schools, however, when he said

that "tests should be designed to reflect changes in what the individual has learned [p. 8]." Not every test should be designed to maximize sensitivity to growth in experience or knowledge. Some tests should measure individual differences in aptitude for growth.

The thrust of the present article is that there is room for both those tests that focus on stable between-individual differences and those that measure progressive within-individual gains. Each of these focuses can be considered a separate dimension of all tests. All tests, to a certain extent, reflect both between-individual differences and within-individual growth. Because of their design and development, however, most tests will do a better job in one area than the other.

The tests that have focused on measuring between-individual differences have been called psychometric tests. Therefore, this dimension of tests will be called the *psychometric dimension*. A test may be evaluated in terms of its psychometric properties, that is, the extent to which it reflects the stable between-individual differences that traditionally have been of primary interest to psychological testing. The other dimension of tests will be called the *edumetric dimension* (see Carver, 1972, 1973). A test may be evaluated in terms of its edumetric properties, that is, the extent to which it reflects the within-individual growth that traditionally has been of primary interest to educational testing. Teacher-made tests, for example, usually focus more on the edumetric dimension rather than on the psychometric dimension.

A failure to keep the psychometric and edumetric dimensions conceptually separate has resulted in a certain amount of confusion when evaluating tests. For example, the American Psychological Association's (1966) *Standards for Educational and Psychological Tests and Manuals* states that "reports of reliability studies should ordinarily be expressed in the test manual in terms of variances for error

¹ The preparation of this article was supported in part by the Office of Naval Research, Personnel and Training Research Programs, Contract N00014-72-C-0240.

Requests for reprints should be sent to Ronald P. Carver, American Institutes for Research, 3301 New Mexico Avenue, N.W., Washington, D.C. 20016.

components (or their square roots) or standard errors of measurement, or product-moment reliability coefficients [p. 29]." This focus on variances and correlation coefficients is of high relevance to the psychometric properties of a test but is completely irrelevant to the edumetric properties of a test. A test may be perfectly reliable from an edumetric standpoint while at the same time it is perfectly unreliable from a psychometric standpoint. The *Standards* does not make this kind of discrimination, however, but reflects a tendency to evaluate all tests from a psychometric standpoint. There is little recognition of the fact that it is quite possible for a test to be extremely good from the edumetric standpoint and extremely bad from the psychometric standpoint.

The remainder of this article is concerned with how to evaluate a test along both the psychometric and edumetric dimensions.

Purpose

PSYCHOMETRIC

If the primary purpose of a test is to measure individual differences, for example, a general aptitude, ability, or trait, then the test should be primarily evaluated using psychometric principles. However, the test may be evaluated from an edumetric standpoint as well.

EDUMETRIC

When the primary purpose of the test is to measure the gain or growth of individuals, for example, the measurement of knowledge, skill, or achievement, the test should be primarily evaluated using edumetric principles. The test may also be evaluated from a psychometric standpoint.

EXAMPLE

The primary purpose of a mathematics aptitude test may be to reflect stable between-individual differences that are useful for predicting achievement in a variety of mathematical tasks. The purpose of this type of test might be to predict, for example, the relative length of time required for eighth graders to learn how to calculate the square root of any number. The primary purpose of this test would be psychometric. However, if a test were developed for determining whether an individual

had learned how to calculate a square root, then the purpose would be primarily edumetric.

Item Selection

PSYCHOMETRIC

The most efficient item from a psychometric standpoint is one with a passing proportion of .50 (i.e., $p = .50$). Items that all students answer correctly or items that no students answer correctly are discarded or revised. The psychometric efficiency of a test is maximized when $p = .50$ because at that point the variance in test scores is largest. Small variances automatically lower psychometric reliability and validity estimates. Another way to select good items from a psychometric standpoint is to use item-test correlations. By correlating scores on each item of a test with the total test score, the items with the highest correlations are selected because they are the best items for discriminating among individuals. Those items that everyone tends to get right or everyone tends to get wrong will automatically have low item-test correlations and will therefore be discarded.

EDUMETRIC

The most efficient item from an edumetric standpoint is one that is maximally sensitive to growth or gain. The best edumetric item is one that shows the most increase in proportion passing from a pre- to a posttreatment condition. One way to select the best edumetric type of items is to administer them in a setting in which the items should reflect change or growth and then select the items that reflect the most gain. The best edumetric items would have p values approaching .00 prior to the treatment condition and p values approaching 1.00 subsequent to the treatment condition.

EXAMPLE

The mathematics aptitude test, mentioned earlier, might be developed by administering a set of items to a group of eighth-grade students and eliminating those items that almost all students answer either correctly or incorrectly. The square-root test might be developed by administering a set of items to one group of students who had never received square-root instruction and to another group of students who had received such instruction. Those items that show little gain would be discarded.

THE

1. The first step in the process of the scientific method is to make an observation or ask a question. For example, you might notice that plants in a sunny location grow faster than plants in a shady location. This leads to a question: "Does the amount of sunlight affect the growth rate of plants?"

score on a test is an estimate of a score on the criterion, then the separate test score is not really unrelated from a psychometric standpoint.

Score Interpretation

PSYCHOMETRIC

Raw scores on a test are usually not interpreted psychometrically because score itself means nothing unless it is compared to an average score either by a deviation from a mean or by the percentage of a normative group. Thus psychometric scores may be z scores, T scores, stanines, percentiles, or any variation of these types of scores. Psychometric scores are developed to provide comparisons between individuals.

EDUCATION

Raw scores on a test may be interpreted educationally. The educational score has meaning in relation to a criterion objective or scale that is a reflection of individual differences. Educational scores may also be converted into psychometric scores to provide additional meaning. For example, an educational score may be converted into a percentile score, a term familiar to provide an estimate of the number of people in a normative group who scored below this particular educational score under similar circumstances.

EXAMPLE

The raw score on a mathematics aptitude test would not be interpreted unless it was compared to the average score of a group. However, the score on the square-root test could ordinarily be interpreted directly because it would mean something in respect to the task of taking a square root. The interpretation of this score would not be relative to the average score of a group.

Sample Evaluation

A sample evaluation is presented here to demonstrate the differences of the psychometric and educational dimensions for evaluating tests. The test was evaluated in the Sequential Tests of Educational Progress (STEP) Reading Test published in 1963 by the Educational Testing Service. This test was chosen because it has been widely used (e.g.,

see Coleman, et al., 1966, and here as this report) and a large number of tests that are in the literature that could be substituted if the psychometric and educational dimensions were used to evaluate the tests.

CONCEPT

The stated purpose of the STEP test is to measure the ability to understand direct statements, to interpret and summarize passages and to critique passages with respect to ideas and presentation of presentation. This purpose appears to encompass the educational dimension more than the psychometric dimension. There is nothing in the purpose to suggest that the test is more relevant to reflecting individual differences with respect to these skills than it is to reflecting gain, growth, or achievement in these skills. This interpretation of the primary purpose of the test is reinforced by the fact that the test is part of an achievement test series, and the test is designed to be used in educational evaluation; the measurement of individual gain or growth in reading would be expected to be more important than individual differences in reading aptitude. Therefore it appears reasonable to expect the test manual to lean more toward the educational dimension than the psychometric dimension.

ITEM SELECTION

The educational dimension was not focused on in the item selection process. Instead, it was stated that the goal was a test with a modal item difficulty of .63 correct. The .63 correct value is really the standard $p = .50$ when a correction for guessing is applied. Therefore, the primary concern in item selection was on the psychometric dimension rather than the educational dimension. If the concern had been on the educational dimension, then the item selection procedure would have been one of selecting those items that reflected the most gain or growth. The test manual did state that the test was designed in light of measurement theory, was not the one guideline for selecting items. A short description of these selection criteria suggested that they were educational. So some educational criteria were probably applied although in an opportunistic manner. If this appears that item selection techniques were used that would tend to create the measurement of a reliable and valid psychometric trait, it is questionable, however, how good the test would be from an educational standpoint.

VALIDITY

At the time that the test was published, there was no validity data collected. It was stated, however, that the publisher expected to conduct validity studies, relating test scores to suitable criterion measures. This suggests that validity would be estimated in the traditional psychometric manner. There is no hint that a validity evaluation would regard the degree to which the test reflected gain or growth, in spite of the fact that the main purpose appears to be edumetric.

RELIABILITY

Only the psychometric type of reliability was estimated; that is, Kuder-Richardson 20 reliability coefficients were reported. The KR-20 is useful for estimating psychometric reliability because it focuses on item variances. If item variances approach zero, the psychometric reliability of the test approaches zero. The standard error of measurement was given, but this reliability estimate is also of the psychometric variety. If the test were to be evaluated from an edumetric standpoint, it would help if there were an estimate of the degree to which the same score on the test could be expected to be made by the same individual under similar circumstances. For example, the average difference between scores on Form A and Form B could be given. It was impossible to estimate the edumetric reliability of this test in the above manner because both forms of the test were never given to the same individuals. The data suggest that the test is psychometrically reliable. Its degree of edumetric reliability is indeterminant.

SCORE INTERPRETATION

The test manual stresses that raw scores are never interpreted. This suggests at the outset that the scores are psychometrically oriented rather than edumetrically oriented. The raw scores are first translated into what are called *converted* scores. The mean converted scores increase with each higher grade between Grades 4 and 14, and this suggests that the converted scores may have good edumetric properties. These scores are subsequently used to determine percentile bands. If the converted scores had been developed to provide an edumetric type of scores, then data regarding the edumetric reliability and validity of these converted scores should have been presented. The manual

for the test never even suggests that one score may be compared with another score to determine the amount of gain or growth. Therefore, it must be concluded that the test provides scores that are of questionable usefulness from an edumetric standpoint.

CRITIQUE OF THE TEST

From an edumetric standpoint, the STEP Reading Test is of an uncertain quality because neither the item selection process, the reliability estimation process, the validity evaluation, nor the score interpretation focuses on the edumetric properties of the test. It may appear to be strange that a major test publisher would attempt to solve an edumetric type of measurement problem using a test designed by psychometric principles. This is not surprising considering that almost all standardized tests have been designed using psychometric principles irrespective of the stated purpose. When psychometric principles are used to develop an achievement test, the result is usually not an achievement test at all but an aptitude test (see Anderson, 1972). Achievement tests would be more reliable and valid if they were developed with a focus on their edumetric characteristics.

Discussion

The measurement of gain or change has been a continual nemesis to psychologists in general and psychometricians in particular (Harris, 1963). Bereiter (1963) stated that it is only with regard to problems in measuring change that he has ever heard colleagues admit to having abandoned major research objectives solely because the statistical problems seemed insurmountable. More recently, Cronbach and Furby (1970) suggested that "investigators who ask questions regarding gain scores should ordinarily be better advised to frame their questions in other ways [p. 80]." Because gain or change is an aspect of science that fascinates most scientists, it is surprising to find that Cronbach and Furby argued that "gain scores are rarely useful, no matter how they may be adjusted or refined [p. 68]." These problems with measuring change or gain always involve correlational, that is, psychometric, models. For example, Cronbach and Furby defined the reliability of gain or difference scores as "the correlation of the score with an independently observed difference [p. 70]." The gain

scores on a perfectly *reliable* edumetric test that everyone failed prior to treatment and everyone passed subsequent to treatment would have to correlate zero with any other variable, thereby rendering the gains as perfectly *unreliable* in Cronbach and Furby's psychometric model. It seems reasonable to agree with Cronbach and Furby that gain scores on a *psychometrically developed test* would rarely be useful no matter how they may be adjusted or refined. However, it is absurd to suggest that gain scores on an *edumetrically developed test* are rarely useful.

On reflection, it is hardly surprising that psychometricians have had so much difficulty with gain scores on tests. If a test is designed according to the best psychometric principles, then it would be somewhat serendipitous if the test scores reflected gain very well. If test scores that measure gain well are desired, then the test should be designed, developed, and evaluated with a focus on edumetric principles. Furthermore, the psychometrician who desires to measure and study gain must recognize that psychometric statistics, such as variances and correlations, are likely to be inappropriate. Use of edumetric principles should yield greater success.

The distinction between the psychometric dimension and the edumetric dimension has always been understood intuitively by experimentalists. For example, in prose-learning research, the researcher may develop 12 multiple-choice questions to determine how much was learned from a short reading passage. The reliability, that is, the psychometric reliability, of such a short test would of necessity be extremely low. However, this type of reliability is never even considered by the experimentalist because he is only concerned with how sensitive the test is to the change or gain that accrues from his experimental treatment. The experimentalist is only concerned with the edumetric validity of the test. The main reason the psychometrician has had problems with measuring gain or change is that the gain or change means that some treatment condition is involved and therefore the psychometrician is entering the domain of the experimentalist. The psychometrician has tried to bring his psychometric test principles with him when he entered the experimentalist's domain, but these principles are inherently inappropriate.

Many psychologists have fostered the use of psychometric test principles in education. Because education generally involves a treatment effect, it

is easy to see how the intuitive edumetric approach of the experimentalist would be inherently more appropriate for education than the individual difference approach of the psychometrician. The danger involved in using the psychometric approach in education is that psychometrically developed tests will be used to measure the effects of education, and education may appear to be ineffective because the tests were not designed or developed to be sensitive to growth. One example of this danger involves the Equality of Educational Opportunity Report (Coleman et al., 1966) commissioned by Congress. This research used psychometrically developed tests and psychometric analyses and found that between-individual differences contribute more to the variance of test scores than between-school differences. This result has been interpreted as having implications for federal policy with respect to school funding (Mosteller & Moynihan, 1972) because schools appear to have little impact on achievement. It has been pointed out that psychometrically developed tests have been designed to produce just this type of a result, so the result should not be surprising nor should it be used to influence federal funding policy.²

Standardized achievement tests are used to evaluate innovative treatment programs in education, and many school systems use these tests to evaluate teachers and schools. These tests are usually psychometrically sound, but they may not be highly sensitive to differences in educational treatment; that is, they may be good aptitude tests but poor achievement tests. Therefore, it is quite possible that the differences between good education and poor education will erroneously appear to be small simply because the tests have been designed to be more sensitive to aptitude differences than to treatment differences.

The increasing development of criterion-referenced tests indicates that the focus in testing is turning more and more to the edumetric dimension. However, it is not generally recognized that a criterion-referenced test may have sound or unsound psychometric properties and that a norm-referenced test may have sound or unsound edumetric properties.

Psychometrics has a long, documented history, an active society, a professional journal, an overwhelm-

² R. P. Carver. "The Coleman Report: Using Inappropriately Designed Achievement Tests." Unpublished manuscript, 1974.

ing influence on testing, and a multitude of statistical techniques and procedures. Edumetrics is little more than an idea. However, there is apt to be little progress in the measurement of gain, change, growth, or achievement unless the edumetric aspects are considered.

Conclusion

When a measure of individual differences is desired, a test that was developed to be maximally sensitive to individual differences should be used. Similarly, when a measure of within-individual gain or growth is desired, a test should be used that was developed to be maximally sensitive to within-individual gain or growth. Most tests are sensitive to both individual differences and to gain or growth, but because of certain design and development techniques, one of these two features is usually focused on. These two primary dimensions of tests have been called psychometric and edumetric.

A test may be evaluated with respect to both the psychometric and edumetric dimensions. Because the psychometric dimension has been focused on traditionally, many standardized tests are used to measure gain or growth without being developed or evaluated from an edumetric standpoint. The danger of this approach is that the psychometrically developed tests may not be sensitive to gain when in fact there is gain.

Miller (1969) encouraged psychologists to give psychology away to other disciplines. It appears that psychologists have been giving away sound psychometric tests to education for many years when education really needed sound edumetric tests. The edumetric dimension of tests has been sorely neglected by psychologists involved in testing. Experimentalists in psychology have known intuitively that psychometric principles are irrelevant and that edumetric principles are needed when measuring amount learned. It is hoped that future

tests will be developed and evaluated with an appreciation of both dimensions so that both researchers and practitioners will have better tests with which to solve measurement problems.

Status of Women in the Psychological Community in the Southeast

A Case Study

ELLEN KIMMEL *University of South Florida*¹

Psychologists are called on increasingly to solve society's problems. One of the most salient of these problems concerns the "minority" status of women. Equal opportunity of education and employment is a familiar slogan and has now even become law.² The problem lies, of course, in implementation of the law—in spirit as well as letter. Eliminating discriminatory admission, hiring, or promotion practices will satisfy the law technically. But the *spirit* of new legislation will not be realized without attitudinal changes encouraging women to utilize new opportunities. Equality for women has been sought on practical as well as moral grounds. Full utilization of the talents of all members of a community is necessary for its health and well-being. This is a legitimate goal for community psychology. Also, because the modification of attitudes is unquestionably "psychology," it is essential that psychological expertise be directed to this issue.

Many segments of the community seek psychological assistance. In this instance, the academic segment of the community was early to seek help, as academic women began to examine their status. Women academic psychologists were contacted for assistance in collecting data on the apparent sexual inequality in employment. As these women became more "aware" of sexual discrimination in all academic areas, including psychology, they began to examine the larger community of psychology itself.

To what extent do women participate in the field of psychology in this country? Before psychologists can guide the community at large toward sexual attitudinal change, surely they must first put their own house in order.

In October 1970, APA's Council of Representatives established the Task Force on the Status of Women in Psychology. Its major effort was to recommend actions based on inequalities already documented nationally by other groups. The 1971 and 1972 reports of Astin's committee made a significant contribution by suggesting ways to combat institutionalized sexism. But local applicability of these recommendations was unclear. Did regional differences in the nature of the problem warrant different approaches to solving it? Even if not, wouldn't the use of people most closely associated with a problem be necessary for its effective resolution?

Assuming an affirmative answer to the latter question and with insufficient information to refute the former, the Executive Committee of the Southeastern Psychological Association (SEPA) appointed its own Commission on the Status of Women in the spring of 1972.³ The Commission was charged to describe the status of women in psychology in the Southeast, to develop an affirmative action plan, and to present a report at the annual meeting in 1973.

Budget precluded a face-to-face meeting of the group's members. Consequently, each agreed to provide a different piece of the puzzle of how and to what extent women contribute to psychology in the

¹ This and the following articles were presented in modified form in a symposium at the meeting of the Southeastern Psychological Association, New Orleans, Louisiana, April 1973. The authors gratefully acknowledge the help of Jane S. Howland.

Requests for reprints of the entire case study should be sent to Ellen Kimmel, University of South Florida, FAO 270, Tampa, Florida 33620.

² Refer to the October 24, 1972, issue of the *Chronicle of Higher Education* for a summary of the five major legislative acts affecting women passed since 1963.

³ Commission members were Ellen Kimmel (Chair), Annette Brodsky, LaMyra Davis, Joan Joesting, Beth Piacente (graduate student), Virginia Pendergrass, Joan Sophie (graduate student), and Judith Worell. Raymond Schrader served as liaison from the Executive Committee of SEPA.

Southeast and to SEPA. We looked at women in the role of faculty, administrators, private practitioners, researchers, graduate students, and SEPA members, through surveys of female and male psychologists, members and nonmembers of SEPA, PhD students, department chairs, and, in one case, a controlled experiment on undergraduates of both sexes.

Our definition of the "Southeast" as a region included states with significant SEPA membership or containing members of SEPA's Association of Department Chairmen. Alabama, Arkansas, Florida, Georgia, Louisiana, Maryland, Mississippi, North Carolina, South Carolina, Tennessee, Virginia, and West Virginia thus comprised our Southeast.

What follows is a summary of the major findings of these studies. Some of our results replicate regionally what others have found nationally. Some of our findings are unique. In advance, it can be said that women psychologists in the Southeast constitute a "minority" group. Not surprisingly, women are underutilized in many ways. On the other hand, we have some suggestions that things may be improving.

Women in SEPA

Approximately 19% (263) of SEPA's members in 1972 were female, while 23.5% of APA's members in 1971 were female. Fourteen percent (23) of SEPA's Association of Department Chairmen are female, but only one woman (2%) chaired a southeastern graduate psychology department. Only eight identifiable (by name) females head any of the 333 graduate psychology departments in the United States.⁴ No member of SEPA's 1973 Executive Committee was female, and there has been only one woman among SEPA's 20 presidents. Female participation at SEPA's 1973 meetings was proportional to their number in SEPA, while 15.5% of APA's participants in the 1970 meetings were women. More women's requests to be on the 1973 SEPA program were denied due to "poor quality" (53% of those rejected) than men's (45% of those rejected).

⁴ Survey by APA Educational Affairs Office, September 1972.

Women in Academe

JOAN JOESTING *Livingstone College*¹

An abundance of studies document the status of women in academe (e.g., Astin & Bayer, 1972; Oltman, 1970), but none has particularly focused on the Southeast. To accomplish this, a questionnaire was sent to the chairs of a sample of 49 psychology departments in the Southeast. Data were sought about women faculty, graduate students, etc., and about the size of the academic institution and department.

Method

All 25 PhD-granting departments in the region were included, and 2 additional non-PhD departments were chosen from each state, 1 from a public and 1 from a private four-year institution. Since the institutions with non-PhD departments also had smaller student populations, they will be referred to as "small" institutions, and the PhD-granting sample as "large" institutions.² The questionnaire was mailed in January 1973 and a follow-up sent in February 1973.

² This sample was developed by a staff assistant (Jane Howland) using the 1973 *Report of Credit Given by Educational Institutions Directory*, American Association of Collegiate Registrars and Administration Officers.

Results and Discussion

Twenty-two of the 25 large institutions and 14 of the 24 small institutions responded. Table 1 gives the number, rank, and salary of female and male faculty with the doctorate for large and small institutions. Women comprised 9% (36) of the 420 psychology faculty with professorial rank and a doctorate in the large institutions and 29% of the 55 faculty in the small institutions. Women in large institutions held 6% (11) of the professorships, 7% (7) of the associate professorships, 12% (18) of the assistant professorships, and 21% (12) of all other PhD faculty appointments. At large institutions, 6 females of professorial rank did not have the doctorate (5 were tenured), while no males with academic rank lacked a PhD. Six female and 5 male non-PhDs were instructors, but because of the small *N*, their salaries will not be discussed. In small institutions, 73% of the faculty with professorial rank held PhDs (16 females, 49 males), and women with PhDs were 22% of the full professors, 25% of the associate professors, and 26% of the assistant professors.

Men with full professorships earned an average of \$1,062 more than women having that rank. How-

ever, the average salary of female associate professors was \$1,419 higher than that of male associate professors. Female assistant professors earned more than male assistant professors. In small institutions, male professors (with PhDs) earned \$3,685 more than female professors, while women associate professors earned \$1,558 more than men in that category. Male assistant professors earned \$803 more than female assistant professors. Since the *N*s are small, these differences may not be reliable. Comparison of salaries of the PhDs with the same rank and sex in large versus small institutions showed differences in favor of the large institutions for each rank, with the greatest difference at the rank of full professor for both sexes. Females have wider salary ranges at the larger institutions than males, but not in the small institutions. It may be that salary differences favoring men are smaller in the large institutions because larger institutions have had more intense and earlier affirmative action activities than smaller, particularly private, institutions. Some larger institutions who responded have completed university-wide salary equity studies to equalize salaries for women and men.

In small institutions, there were 9 female and 10 male faculty without doctorates. Their salaries

were only slightly lower (within rank) than their PhD counterparts. Women assistant professors (5) earned \$1,037 less than men (3). Only 1 person without a PhD (a woman) held the rank of associate professor.

Twenty-five percent of the women and 63% of the men in large institutions had tenure, as compared to 59% of the women and 44% of the men in smaller institutions. Since few women in large institutions were in the upper ranks, it was not surprising that fewer had earned tenure. It is possible that women in small schools are given tenure (and rank) instead of more money. Or, women may have fewer opportunities to move to a better (bigger) institution.

Concerning special recruitment of women faculty, there were some interesting differences between large and small institutions. Eighty-two percent of the large, but only 7% of the small, institutions responded yes to the question, "Has your *department* made any special efforts to recruit women psychology faculty?" Eighty-two percent of the large and only 22% of the small answered yes to the question, "To your knowledge is your *institution* actively trying to hire more women faculty?" One department (large) reported that its institution actively discouraged the hiring of women faculty. Many departments advertised their interest in women and minorities, or sent recruitment letters to this effect. Others listed vacancies with the Association for Women in Psychology. One department head wrote, "We try to find a woman first . . . then look for a man if we can't find a girl [*sic*]." Large departments appeared to be sensitive to the need for hiring more women and are trying to do so. One small institution reported that it was willing to hire either a male or a female and, in fact, did interview women the last time it recruited. Fifty percent of the large and only 7% of the small institutions reported antinepotism regulations, a major obstacle to the hiring of women faculty. Nine percent of the large and 14% of the small did not answer this question at all, and one institution (small) responded ambiguously. There probably still are *unwritten* antinepotism rules. Those remaining departments officially proscribe persons related in the first degree of consanguinity from working either in the same administrative unit and/or directly supervising the other. One department chair indicated that such regulations led to the loss of "four superb faculty persons that we otherwise would have hired."

Three questions concerned graduate students. The large institutions reported that 41% (93) of their MA students and 37% (523) of their PhD students were women. Small institutions indicated that 47% (151) of their MA students were female. Sixty-one percent of the large, but only 36% of the small, institutions permitted graduate students to register part time. The APA Task Force (1973) survey found that 54% of graduate departments permitted part-time registration. The Southeastern Psychological Association (SEPA) departments reported that there were few apparent differences between the attrition rates of women and men students. One institution claimed higher attrition rates for females, but did not send the data. There was no feeling a priori that women are less likely than men to complete graduate training. Since no "hard" data were presented in response to our request, it is assumed that departments have none. It is unfortunate that records of applications and admissions are infrequently maintained for any period of time.

None of the large institutions and only one of the small institutions have an undergraduate major in women's studies, although 32% of the large and 14% of the small institutions have women's studies programs. Thirty-two percent of the large and 14% of the small institutions offer a psychology of women course. At large institutions, female faculty, more frequently than male, taught these courses. At small institutions, male faculty were more likely to teach the women's studies courses, probably because few female faculty are available. One respondent said, "We may, when we hire a female or two." Also, 22% of the large and 29% of the small departments indicated that they were planning to offer such a course in the future. One department with no such plan said, "No, the reason is simple: There *just* isn't that *damn much difference* between men and women . . . ! Such courses drive wedges between us where understanding, harmony, and equity are needed!!!!!" However, APA's Task Force on the Status of Women (APA, 1973) recommended that "colleges and universities should offer (a) general education courses and programs that inquire into the psychology of women and the forces affecting their status and (b) an opportunity for in-depth study, at both undergraduate and graduate levels, of the psychology of women [p. 613]." Thirty percent (25) of the large departments in APA's survey reported offering a course on the psychology of women in the 1971-1972 aca-

demic year or before. Since 33% already offered and 29% of SEPA's sample planned to offer a psychology of women course, the Southeast is in step on this issue.

Conclusion

Women psychology faculty in the Southeast are few in number in large as well as small institutions, more so in the larger institutions. A comparison of our data with that of APA's (1973) survey showed slightly less representation of women on faculties in the Southeast than nationally. Our study indicates that salaries of women full professors are substantially lower than those of men, but that the reverse is true for associate professors. No differences in salary were found for assistant professors. There was a suggestion of greater differences in pay between women and men at small institutions. Salaries in general are higher in all ranks for both men and women in the larger institutions. With women seldom holding higher ranks in large institutions, tenure was also more difficult for them to earn. In small institutions, women were better able to achieve both high rank and tenure.

As in the APA study, our data showed that a substantial number of MA students are women, but women are still underrepresented among doctoral students. We found no evidence supporting the

notion that women show higher attrition rates than men in graduate school. Departments verbalized no impressions that "women are a bad risk." Southeastern graduate departments permit part-time study as frequently as departments nationally, but there is room for improvement for both.

The status of women was related to the size of the department and institution. Women are employed as faculty members in small institutions roughly in proportion to the percentage of doctorates women earned in psychology. This is not true in large institutions. Overall, accordingly, women remain underrepresented in academe. Women in small schools have a better chance to attain tenure and promotion than women in large schools, although their salary status in relation to men's is worse. Finally, the substantial number of psychology of women courses and women's studies programs, especially in large schools, shows an awareness of the need to include women in the curriculum.

Women as Graduate Students

ANNETTE BRODSKY *University of Alabama*¹

The survey reported here explored areas of potential discrimination that are not evident from the usual statistical reports. Thus, many items were selected in open discussion with several of the wo-

men graduate students at the University of Alabama, Tuscaloosa. Emphasis was placed on gathering information from students themselves, about such things as their assignments, interpersonal relationships, and the encouragement they receive. The question was asked, "How much are these 'soft' signs of discrimination felt by graduate students and in what ways?"

¹Detailed information may be obtained from Annette Brodsky, Department of Psychology, University of Alabama, Box 2968, University, Alabama 35486.

Method

A 45-question survey was sent to 24 of the 25 (one was omitted unintentionally) departments in the southeastern United States that offer PhD programs in psychology. Each was requested to distribute 10 questionnaires in the following manner:

Make an alphabetical listing of all currently enrolled female graduate students and divide the total number of them by five. For example, if you have fifteen female graduate students currently enrolled, divide by five and then select every third name. Then use the same procedure for the male graduate students. If any of the students who are randomly selected are away from campus (such as those on internships) please forward their form promptly.

Thus, five female and five male doctoral students were selected in each department, with a potential total of 240 student replies. Of those, 150 questionnaires, from 77 males and 73 females, had been received two months after the questionnaire was distributed.

We had no control over the compliance of the department chairs (all males) in distributing the questionnaire. To the usual problems associated with return rates, we must add one more source of possible bias: An uncooperative chair meant the loss of 10 respondents. However, replies contained postmarks from all the states that comprise the southeastern region, except Mississippi which has no PhD program in psychology.

Results and Discussion

The sexes were remarkably similar in age (females: range 21–39 years, mean age 25.3 years; males: range 21–41 years, mean age 26.4 years); Graduate Record Examination (GRE) scores (female median, 1,208; male median, 1,245); and undergraduate grade point average (GPA) (female, 3.26; male, 3.17). Psychology doctoral students in the Southeast tend to come from the Southeast (females, 56%; males, 39%). As Table 1 shows, programs were selected mainly for financial aid, department characteristics, and faculty characteristics. More women (19%) were influenced by a spouse or loved one than men (1%).

Only one item concerning motivation to enter psychology strongly suggested a sex difference. Thirty-two percent of the males checked income potential but only 12% of the females. Also, men slightly more often than women checked prestige of the field, freedom of hours, and freedom from supervision.

In terms of careers within psychology, there were few sex differences. Ten percent of the males said they were seeking administrative jobs, compared to 1% of the females. Women who planned to enter clinical fields saw themselves more likely to work in educational or institutional settings, while more

males (29%) than females (18%) planned to go into private practice. (See Pendergrass's results, pp. 533–535, this issue.)

Table 2 shows that parents and spouses were sources of encouragement to enter psychology for about 25% of both sexes. Friends were more of an influence for females. The most frequent source of encouragement for both sexes was male teachers (males, 40%; females, 33%). However, female teachers were reported as an influence by 33% of the females, but by only 16% of the males. If same-sex role models are important to college students, the small number of female professors may result in fewer females applying to graduate programs. Thirty-nine percent of the males and 31% of the females entered with no specific source of encouragement.

When students were asked what they expected their major duties to be in 10 years, females ranked clinical work highest (60%), then teaching (49%), research (34%), service (20%), and administration (12%). Males, however, selected clinical,

teaching, and research activities with equal frequency (44%), and then administration (29%).

In the area of family responsibilities there were some expected sex differences. Only 27% of the 150 respondents were parents: Twice as many men, 18%, as women, 9%, had children. This agrees with other findings on parenthood and graduate school enrollment, namely, that the presence of young children at home is negatively correlated with graduate enrollment for women (Feldman, 1972). Sex differences were striking in the percentage of total nonfinancial responsibilities for the child: males, 41%; females, 64%. Thus, while psychology PhD students are not often parents, the responsibility weighs more heavily on graduate student mothers than fathers. This is related to the additional finding that more male graduate students were married (65%) than female graduate students (42%). This is true nationally also (Feldman, 1972). Because the males and females did not differ in age, it may be that females who marry and raise children do not attempt to enter graduate school in the first place. Because married women PhD psychologists have children at the national rate (Fields, 1972), it is likely that female graduate students simply delay marriage and families.

Sex differences regarding child care were unclear. Both males and females used their spouses (males much more so) as baby sitters and felt that lack of time to spend with the children because of graduate student duties was an important problem. Cost of child care was less of an issue for females than males, but the numbers were too low to draw any conclusions. Women reported guilt more often for not participating in professional opportunities. Men reported the reverse—guilt for not participating in family activities. Sex role stereotypes in the ranking of responsibilities between the sexes are still apparent in that women placed family and men placed professional obligations as primary.

Our data did not indicate discrimination against women in areas of graduate student experience where it is often suspected. Males and females equally reported receiving fellowships and research and teaching assistantships. Assistantship duties were also similar for the two groups. More males reported full teaching responsibility, while females were more often teaching assistants.

Table 3 shows that 21% of the males reported feeling sexually discriminated against on grades, while only 8% of the females did. Females felt more discrimination in research assignments and assistantships (14% females versus 3% males). Most striking was the fact that 40% of the females but only 12% of the males reported feeling sex discrimination in the attitudes of the faculty.

Table 4 shows that men and women reported equal encouragement to attend meetings and publish research and that females were more often encouraged to present papers than males. On the other hand, slightly more males than females reported an invitation to accompany a faculty member on a professional trip. Fifty-two percent of the males but only 41% of the females were offered authorship for research participation. Males were more often encouraged to meet important scholars outside the department (34%:19%) and to teach a course, or supervise students (36%:23%).

There was no apparent difference in social treatment between the sexes. Two thirds of the graduate students of both sexes were invited to at least one party by a faculty member. The current group of female graduate students in psychology departments in the Southeast seemed to feel as secure about their presence as their male counterparts.

Conclusion

There are far more similarities than differences between women and men graduate students in the

TABLE 4

Southeast. Glaring discrimination is *not* perceived to be present by women psychology graduate students as a group. The absence of married women and/or older women, especially those with children, and their relative absence in certain selective, high-prestige student positions were somewhat suspect since the age, GPA, and GREs of the women were so similar to those of the men. The absence of women's administrative aspirations was discouraging, particularly because they indicated feeling secure in their status with regard to their peers. Since women are more likely to have a discontinuous school pattern due to child rearing (Hembrough, 1966), one would expect a higher percentage of women than men in the sample to be in the over-30 age range. However, 8 women and 16 men were 30 or over. The modal age for both groups was 23, but by the age of 28, women had far less representation (9 women over 28 as opposed to 21 men). Also, almost all of the respondents were full time, which suggests discouragement if not outright prohibition of part-time training, although 61% of the department chairs (answering their own survey) in-

dicated that part-time graduate study was permitted.

The similarities between the sexes in such things as financial aid, areas within psychology pursued, assignments, and general encouragement from faculty lead to the general conclusion that women graduate students in the Southeast feel that they receive equal treatment to men. While they may feel as secure about their professional presence as the males do, they perceive personal attitudes from the faculty which indicate that women in psychology graduate programs in the Southeast are not yet fully accepted as individuals.

Women as Experimenters

BETH STEARNS PIACENTE *University of South Florida*¹

A great deal of evidence has accrued during recent years to support the feminist allegation that both overt and covert prejudice against women seeking, or functioning within, professional roles exists not only among the general lay public but at the professional level as well. For example, Goldberg (1968) gave female college students identical arti-

cles in a variety of disciplines (e.g., law, education, city planning) to evaluate, but varied the sex of the author. Articles were judged to be less valuable and their authors less competent when the author was female.

Findings seemingly inconsistent with these results have been reported by Pheterson (1969), who replicated the Goldberg (1968) procedure with the exception that the subjects were middle-aged, "uneducated" women. Those subjects judged the articles allegedly written by women as nearly equal to those allegedly written by men. A further study conducted by Pheterson, Kiesler, and Goldberg (1971) may shed some light on the apparent dis-

¹ This study is based on a thesis submitted by the author in partial fulfillment of the Master of Arts degree at the University of South Florida. More information may be obtained from Beth S. Piacente, Department of Psychology, SOC 326, University of South Florida, Tampa, Florida 33620.

crepancy between the Pheterson (1969) study, which found women to be judged of equal if not greater competence than men, and the Goldberg (1968) study, which found greater perceived competence in men than women. Pheterson et al. asked women college students to judge a set of paintings. The sex of the artist and the independently judged quality of the production (whether the painting was described as an entry or a winner in an art contest) were systematically varied. It was found that when the subjects were told that the paintings were simply entries, paintings by male artists were rated better than those by female artists. However, no sex-related differences were found in the ratings when subjects were told the paintings were winners. In the Goldberg (1968) study there was much greater ambiguity as to the competence of the women and thus, in the absence of further information about the women they were judging, subjects in the Goldberg study assumed the women to be less competent than the men.

Two generalizations are suggested from the literature. First, the professional efforts of females will tend to be judged less favorably than those of males, provided some ambiguity exists regarding the competence of the individuals judged. Second, based on the observations of such researchers as Silverman, Shulman, and Wiesensthal (1972) or Rosenthal (1967), it appears that when women function (or are perceived to function) with relatively unambiguous competency they do so at the "cost" of losing some measure of their femininity.

The purpose of the present study was to evaluate experimentally some implications of those two generalizations. The evaluative perceptions of undergraduate psychology majors regarding the performance of female and male experimenters were studied in a situation where competency was systematically manipulated.

Method

SUBJECTS

The subjects were 214 females and males in the introductory psychology course at the University of South Florida.

EXPERIMENTAL DESIGN

The design included four between-subject variables, varied factorially, and one hierarchical variable. The between-subject variables were (a) sex of the videotaped experimenter; (b) manner of the videotaped experimenter (competent or incompetent); (c) sex of the experimenter showing the videotapes; and (d) sex of the subjects. The hierarchical variable was the *persona* (e.g., the performance,

appearance) of the four confederates who played the roles of the videotaped experimenter. Two female and two male confederates each made one videotape in which they acted competently and a second videotape in which they acted incompetently. The confederates were unaware of the major hypotheses of the study.

DEPENDENT MEASURE

The dependent measure was a 20-adjective (listed in Table 1) semantic differential scale. The instructions were the same as those given by Osgood et al. (1957).

PROCEDURE

The subjects were shown the videotapes in groups of 10 to 25. They were told that the videotape was of undergraduates who were being trained as experimenters and that the experimenter wanted the impressions of a group of people who would be similar to the subjects in the actual experiment. It was further explained that the experimenter seen in the videotape was not aware that she/he had been videotaped through a one-way mirror. The videotape was then shown. After viewing the tapes, the semantic differential was administered with instructions to rate the experimenter on each scale. Approximately one week after the completion of the study all subjects were debriefed.

VIDEOTAPES

The videotapes were approximately 15 minutes in duration. The experiment conducted in the tape was supposedly designed to measure subjects on physiological responses to stress, namely, instructions to administer high levels of shock to a laboratory white rat. A complete description of the apparatus, procedure, and behaviors displayed by the experimenters can be found in Penner, Hawkins, Dertke, Spector, and Stone (1973). In the competent condition, the experimenters acted in a confident, self-assured manner, made no mistakes, and remained calm even when, on the seventeenth trial, the rat seemingly was seriously injured. In the incompetent condition the experimenters started the experimental session late; had an incorrect list of the subjects' names; did not provide an adequate number of chairs for the subjects; had difficulty attaching the physiological sensing electrodes; read the instructions haltingly, suggesting that they were unfamiliar with them; were unable to operate the equipment on the practice trials; and became extremely agitated and distressed when the rat was apparently injured.

Results

A varimax rotated factor analysis (Mulaik, 1972) was performed on the 20 bipolar adjectives, collapsing across between-subject and hierarchical variables.² Those adjectives that loaded together on the same factor were combined and the subjects' responses to these adjectives were summed in order to yield a single score. These scores were then

² Two additional factor analyses were conducted collapsing across all variables except the manner of the experimenter. The factor structure and loadings were essentially the same for all three analyses.

TABLE 1

*Summary of Significant Sources of Variance
for Twenty Semantic Differential
Bipolar Adjectives*

Adjectives	Sources of variance
Active-Passive	ACD
Attractive-Unattractive	A
Complex-Simple	—
Competent-Incompetent	C

Good-Bad	A, C
Hard-Soft	C, AC, ACE
Impulsive-Deliberate	C, ACD
Masculine-Feminine	A, C, AC, CD
Positive-Negative	C
Professional-Novice	C, BC(A)
Serious-Humorous	C
Severe-Lenient	C, E, AC
Strong-Weak	C, AC, DE
Successful-Unsuccessful	C, B(A)
Wise-Foolish	C, BD(A)

Note. All F ratios shown were significant at $p < .025$ or beyond. A = sex of videotaped experimenter; B = "persona" of videotaped experimenter; C = manner of videotaped experimenter; D = sex of experimenter showing videotapes; E = sex of subjects.

subjected to a five-way analysis of variance described above.

In order to simplify the analyses, subjects were randomly eliminated until equal numbers in each cell were obtained. All analyses were based on the responses of 80 female and 80 male subjects.

In the preliminary analyses it was found that the procedure of combining those adjectives that loaded together introduced excessive error variance on the sex of the videotaped experimenter variable. That is, although some of the adjectives that had been combined discriminated between female and male videotaped experimenters, others did not discriminate. Since sex of the videotaped experimenter was a crucial variable in this study, 20 separate analyses of variance were conducted.

Since many of the semantic differential items were intercorrelated, traditional statements about the probability of committing a Type I error due to multiple independent tests of significance did not seem appropriate. However, in order to reduce the possibility of Type I errors, a relatively stringent α level was chosen (.025). Fisher's least significant difference (LSD) test, with the significance level set at .02, was used for all subsequent analyses.

Table 1 presents a summary of the 20 analyses of variance. As can be seen from this table, 36 out of the 460 possible F ratios were significant at or beyond the .025 level. In the interest of economy, only those F ratios that are germane to the hypotheses of interest will be discussed.

All of the following significant main effect F ratios had 1/128 degrees of freedom (df). Competent experimenters were seen as significantly different in the expected direction from incompetent experimenters on 14 of the 20 bipolar adjectives. The sex of the videotaped experimenter yielded significant F ratios on four adjectives. Males were seen as *better* and more *masculine* than females, while females were seen as more *excitable* and more *attractive* than males. The sex of the subjects viewing the videotapes yielded one significant main effect. Males rated all experimenters as more *severe* than did females. Individual videotaped experimenters differed only on the bipolar adjective *successful-unsuccessful*.

Significant F ratios (each with $df = 1/128$) were obtained for the following first-order interactions. Again, using the LSD test, it was found that male incompetent experimenters were seen as *harder*, *stronger*, and *calmer* than female incompetents. On the other hand, female competents were seen as more *severe* than any other experimenters. Incompetent females were seen as more *feminine* than were competent females. Also, it was found that males rated male videotaped experimenters as more *efficient* than female videotaped experimenters (females did not discriminate on this adjective). When subjects were run by male experimenters, they perceived the experimenter functioning under the incompetent condition as more *feminine* than under the competent condition, a difference not present when a female experimenter conducted the actual experiment.

Two second-order interactions germane to this study were found, again each with $df = 1/128$. Male subjects did not discriminate between competent and incompetent videotaped male experimenters on the hard-soft dimension, but did rate incompetent female experimenters as *softer* than competent female experimenters. Female subjects discriminated between competent and incompetent experimenters within sex, but did not discriminate within "manner" across sex on this bipolar adjective. The second interaction showed that when subjects were shown videotaped female experimenters by a female experimenter they did not dis-

criminate between competent and incompetent conditions on the bipolar adjective *impulsive-deliberate*; however, subjects did discriminate between competent and incompetent experimenters on this dimension on all other conditions.

Approximately 10% of the subjects suspected that the purpose of the study was other than that which was given; however, none of these individuals was aware of the true purpose of the study.

Conclusion

The results of this study tend to confirm the hypothesis that when there is little ambiguity as to their competence, women and men are judged to be equally competent, but when there is reason to doubt competence, women are perceived as much less competent than men—more so by men than by women. In addition, competence in women is accompanied by a loss in femininity (in the view of others) and incompetence is accompanied by an increase in perceived femininity. To the extent that these results possess external validity they may offer a partial explanation of the greater "dropout" rate among female graduate students in psychology or other fields (Creager, 1971) and the dearth of women psychologists in highly prestigious academic settings which Joesting's (pp. 520-523, this issue) and Kimmel's (pp. 536-539, this issue) studies of the Southeast and other national surveys have documented.

The results of this study may be interpreted as showing that a woman who achieves competency in her chosen field may do so at the cost of losing

those characteristics that may be popularly considered desirable in heterosexual and/or social interactions. It may be that women pursuing a professional career become cognizant of this cost and decide not to pay it. Further, even if a woman decides to pursue a professional career, she may face the difficulty of being assumed incompetent until she clearly demonstrates that this is not the case. Current trends toward hiring greater numbers of women in professional positions may alleviate the difficulty of proving competence; it may not, however, alleviate the cost to a woman of being perceived as competent.

Women as Scholars

JOAN SOPHIE *University of South Florida*¹

Publication in scientific and professional journals is generally regarded as an index of scholarly pro-

¹ This study is based on a thesis submitted by the author in partial fulfillment of the Master's of Arts degree at the University of South Florida. More information may be obtained from Joan Sophie, Department of Psychology, SOC 326, University of South Florida 33620.

ductivity and is frequently a requirement for academic employment and promotion. Differences in publication rate between women and men could account, therefore, for their differential status in academe evidenced by the decreasing proportion of faculty members who are female at the higher aca-

demographic ranks (see Joesting, pp. 520-523, this issue; APA, 1973).

Astin and Bayer (1972) found the correlation between academic rank and publication to be .49. However, when other relevant variables, including publication, were partialled out, there remained a partial correlation between sex and academic rank of .17, which is significant. While publication is an important determinant of academic rank, women who publish as much as men still do not achieve comparable rank. This discrimination itself could lead to further discrepancies in productivity, because the time and facilities for conducting research, as well as the motivation to do so, would be less for those kept at a lower academic rank.

Simon, Clark, and Galway (1967) examined the effects of marital status and sex on publication and academic rank. Women were divided into three categories: unmarried, married without children, and married with children. Men could not be subdivided because almost all were married and had children. While there were many significant differences among these groups, they were similarly productive. Married women were more likely to publish at least one article than men or single women, and men were more likely to publish at least one book. Thirty-five percent of the men and only 25% of the women had received at least one grant. It may be that the difference in percentage receiving grants, for whatever reason, accounts for the differences in book writing.

Guyer and Fidell (1973), sampling PhD women and men psychologists from the 1968 APA *Directory*, found that men published an average of .61 papers per year compared to .21 for women, a difference that was significant, but that occurred only at the full professor level. When age, academic position, rank of institution, and theoretical or applied interest were partialled out, no remaining difference in rate of publication was left. They concluded, therefore, that there were no differences in publication between women and men.

The present study is similar to Guyer and Fidell's, except that it was limited to psychologists in the Southeast (members of the Southeastern Psychological Association, SEPA), included non-PhDs, and obtained information directly from them by questionnaire. The present study looked at sex and various demographic, educational, employment, and scientific communication variables as predictors of rate of publication.

Method

The names of 110 women and 110 men were randomly chosen from SEPA's 1972 membership list. They were sent a questionnaire, "Characteristics of Academic and Non-academic Psychologists," in December 1972. Care was taken to avoid identifying the study as a status-of-women project by choice of title and contents of the cover letter, a procedure considered necessary in order to avoid bias. Five weeks later a reminder letter was sent. Sixty-five women (59%) and 58 men (53%) responded.

Questions covered four areas: demographic information, education, employment, and scientific communication. Demographic variables included age, sex, marital status, number of children, each parent's education and occupation, degree of religious emphasis during childhood, number of siblings, and birth order. Education variables were highest degree and date received, and academic honors, awards, and honor societies. Employment variables included primary work activity; place of employment; full or part time; number of years employed as a professional psychologist; rank order of various types of work activity: administration, counseling, research, teaching, etc.; and, for those who were teaching, information on courses taught and students advised. Scientific communication variables consisted of number of grants applied for and received, membership in professional and scientific societies, attendance at professional and scientific meetings, oral presentations, number and type of publications, and order of authorship.

A multiple regression program was used several times, varying the specific independent variables included each time and also varying the dependent variable, from number of journal publications to total number of publications of all kinds. In addition, separate analyses were performed for women and men, again using a number of selections of independent variables. Since the choice of dependent variable did not affect the results, only the results for number of journal publications will be discussed below.

Results and Discussion

Women and men in the sample did not differ significantly in age or in the date on which they received their highest degree (see Table 1). There were significant differences, however, in education, place of employment, marital status, and basic versus applied area of specialization. Only 51% of the women, in contrast to 81% of the men, had PhDs; more men (48%) were employed in universities than women (32%); and, finally, more men doctorates (47%) specialized in basic areas of psychology than women doctorates (37%). All of these findings are consonant with the other surveys reported here, with APA's (1973) as well as with other national surveys.

Women in our sample published significantly less than men: The mean number of journal articles published by men was 6.0 compared to 2.4 for women. However, when the effects of variables that contributed more to the regression equation than sex were partialled out, the remaining correlation

between sex and number of publications was negligible (.07).

Variables included in this study accounted for most of the variance in publication, with predictability greater for men than for women. The major regression equations accounted for 81% of the variance in publication for men ($R = .90$) and 64% for women ($R = .80$). These equations used the independent variables of age, highest degree and date received, and all of the suitable employment and scientific communication variables. In addition, marital status and honors were included in the analysis for women, but not for men, because they had been found previously to have predictive value only for women. Other demographic variables, such as parent's occupation or religious training, were eliminated for both sexes because they had little effect when added to the educational and employment variables. The variables that contributed most to the regression equation are listed in Table 2. Although the order of importance of the different variables was not the same for women as for men, the same variables were, in general, important for both. Not surprisingly, the person who published most was likely to have a PhD, work in a university, be involved in guiding graduate students' research and in doing her or his own research, be a member of several scientific societies,

make frequent oral presentations, and apply for and receive research grants. Only two, time spent writing and number of oral presentations, of the corresponding correlations listed in Table 2 are significantly different for women and men. Both were more highly correlated with publication for men than for women.

Guyer and Fidell also reported greater predictability for men than for women. Perhaps since the system of achievement in academe is designed for men, the variables of this system predict their career patterns better than they predict those of women. For women there is a conflict between the academic pattern and the life pattern they are expected to follow as women. This conflict can also be seen in the large difference in the proportions of each sex who are married and in the lesser percentage of married women who have children compared to married men. (In our sample, 75% of the married women and 85% of the married men had children.)

In order to determine the independent effects of the demographic and education variables, a separate multiple regression analysis was performed using just these variables together with place of employment. The results of this analysis are shown in Table 3. These variables accounted for 48% of the variance in publication for women ($R = .70$)

and 40% for men ($R = .64$). Marital status contributed significantly to the multiple regression equation for women, in that single women were more likely to publish than married women, although the zero-order correlation for marital status was not significant. Marital status did not contribute to the regression equation for men since men were so homogeneous on this variable.

The number of academic honors received correlated significantly with number of journal publications for women, but not for men. This difference in correlation was significant. For women, even with highest degree partialled out, the remaining correlation between honors and publication is .25, which is significant ($t = 2.064$, $df = 62$, $p < .05$). These results are compatible with those reported by Simon et al. (1967), although the measure used was different. They compared the number of fellowships received and membership in honor societies, and found that in the social science area, 8% of the women, compared to 4% of the men, had received at least one fellowship, while 35% of the women and only 14% of the men were members of an honorary society. A motivational factor may be responsible for these results: Only the most highly motivated women would achieve honors or publish, which in turn may have promoted greater self-confidence to develop their careers and publish more, despite role conflicts and discrimination.

Conclusion

Men published significantly more than women. However, the large difference in education between

women and men accounted for most of the differences in publication. Because education was the crucial variable, the importance of developing new approaches to graduate education in psychology to encourage the full participation of women becomes even more apparent. The institution of employment and one's position in that institution were also shown to be of great importance in predicting publication in this study. Thus, discrimination against women in academe, which forces them into less favorable employment, reduces their opportunities for scholarly accomplishment, which in turn makes them less able to compete for more desirable positions.

Those women who managed to achieve the same education and employment as men also published as much as their male counterparts, despite the difficulties of role conflicts, lack of professional socialization or sponsors, and inadequate access to informal communication discussed by White (1970).

The possibility exists that differences in publishing were due to simple discrimination by journal editors (predominantly male) against female authors. Outright rejection of a manuscript because a female name appears on it is difficult to imagine. However, more subtle, unconscious discrimination may occur in that women may choose topics and/or present their research in ways that men may consider unimportant and/or inappropriate. Sociologist Pauline Bart (undated) found that most of her male colleagues disapproved of her choice of depression in middle-aged women as a topic of research. She also had great difficulty in publishing the results of her research. To the extent that women in psychology, for whatever reasons, do publish less than men, our discipline suffers the loss of their full potential contribution.

Women as Clinicians in Private Practice

VIRGINIA E. PENDERGRASS *Miami, Florida*¹

Studies of the role of women in the professions report discriminatory practices in graduate education (Astin, 1972; Women's Bureau, 1969); perception of professional competence (Pheterson, Kiesler, & Goldberg, 1971); and employment in universities (Fidell, 1970). Female psychotherapists, however, might be expected to hold a preferred status, because helpfulness, nurturance, warmth, and concern, traditionally attributed to females (Kagan, 1964), would be assets.

In this survey, psychologists in major southeastern cities were polled concerning personal characteristics and private practice activities. The objective was to describe clinicians in private practice, with special emphasis on sex differences.

Method

SURVEY POPULATION

Questionnaires were mailed to all psychologists listed in the yellow pages of cities in states represented in the Southeastern Psychological Association (SEPA), unless the listing clearly indicated nonclinical status. Thirty listings were identifiable as female, and 157 were identifiable as male. Sixty were unidentifiable as to sex, but were assumed to be distributed in proportion to the identifiable sample. The estimated total number of females contacted, therefore, was 40 (16.2%) and the estimated number of males was 207 (83.8%). This percentage of females approximates the percentage of PhDs in psychology awarded to women in 1960 (Astin, 1972). The private practice of psychology, therefore, did not appear to be a "woman's profession," in that inordinate numbers of women are not attracted to it. Of questionnaires mailed, 44.9% were returned, with approximately equal proportions of females and males responding.

QUESTIONNAIRES

Questionnaires asked for the following data:

1. Personal data, including age, sex, extent of practice, degree, publications, awards, and honors;
2. Characteristics of practice, such as extent of practice, income, sources or referrals, type of clientele, motivation for entering practice, and original career goals. Only responses most often ranked first are reported.

Results and Discussion

EXTENT OF PRIVATE PRACTICE

Fifty percent of the women and 73.4% of the men were in full-time practice. Men are, thus, more heavily involved in private practice as a profession than women. It has been found that competitive, aggressive aspects of work may be feared or rejected by women (Horner, 1969) and these aspects of private practice may be unappealing to women. Another explanation of this finding is that the greater responsibility women may have for children and home may limit career commitment.

Since the sample of women was small, and since women in part-time practice represented a significant part of the sample, part-time and full-time practitioners were pooled for further comparisons.

PERSONAL CHARACTERISTICS AND ACHIEVEMENTS

Average ages for women and men ($M = 45.9$ and 44.9 , respectively) and length of time in practice ($M = 10.37$ years for men, $M = 11.44$ years for women) were similar. All but one woman and two men had PhDs. Approximately equal proportions of women and men had received achievement awards (25.0% of women and 20.4% of men) and 18% of both groups had Diplomate status. Women had an average of 2.63 and men 5.76 publications, a difference attributable to a few men in academic or industrial settings who produced large numbers of publications.

AVERAGE INCOME LEVEL

Table 1 shows that the differences in reported earnings for women and men in the first years were small, favoring men, and that men showed consistent economic growth while women did not. Overall average incomes were \$10,000-\$15,000 (mean rank = 3.5) for women and \$15,000-\$25,000 (mean rank = 4.7) for men. No woman made more than \$50,000, while 12 men did. These differences may be due to women therapists holding part-time jobs in conjunction with part-time practice, which may be low paying and offer few promo-

¹ More information may be obtained from Virginia E. Pendergrass, No. 111, 1950 Brickell Avenue, Miami, Florida 33129.

TABLE 1

Average Rank of Income for Female and Male Therapists by Years in Practice

Sex	Years in practice			
	0-3	4-10	11+	Overall
Females (<i>N</i> = 16)	3.4	4.0	3.2	3.5
Males (<i>N</i> = 94)	3.9	4.6	5.1	4.7

Notes. Categories, in dollar amounts, are 1-1.9 = under \$8,000; 2-2.9 = \$8,000-\$10,000; 3-3.9 = \$10,000-\$15,000; 4-4.9 = \$15,000-\$25,000; 5-5.9 = \$25,000-\$50,000.

tions, or it may be that, when women experience difficulties in building clientele and sources of referrals over many years, they become less competitive and adjust their performance and fees downward. Finally, it is possible that women attach less importance to income than men and engage in activities in their practice that do not pay off economically. Brodsky's finding (see pp. 523-526, this issue) that male students checked income potential as a reason for entering psychology more often than females supports this hypothesis. However, involuntary salary limitations on women would demonstrate significant discrimination.

SOURCES OF REFERRALS

Both females and males received most referrals from medical or osteopathic physicians (46.7% and 44.6%, respectively), former clients (20.0% and 27.3%), and government agencies (13.3% and 3.0%). Since women received referrals from the same sources as men, and since both listed medical and osteopathic physicians as primary (a profes-

	% female (<i>N</i> = 16)	% male (<i>N</i> = 94)
Clinical, private practice	25.0	28.7
Clinical, institution	12.5	20.4
Academic, emphasis on teaching	31.3	17.0

sion dominated by men), women do not appear to suffer discrimination from other professionals.

PRIVATE PRACTICE CLIENTELE

Both sexes reported seeing individual adult females most often as clients (see Table 2). Males more frequently saw children or individual adult males, while women therapists more often saw couples or families. The expected stereotype of women therapists seeing children primarily was not found. Perhaps the role of the therapist in her/his own home may lead the therapist to diagnosis disorder in children differently. Women therapists may seek explanations of children's difficulties in total family interactions or in marital strife, while male therapists may deal with the child as an individual. Or parents may go to women therapists for sympathetic arbitration of marital and family difficulties, but take individual problem children to male therapists for discipline.

Only male therapists listed adult males as primary clientele. Unfortunately, if female clients

Percentages of Female and Male Respondents Ranking Types of Clientele as Primary Clientele

Type of clientele	Sex	
	% female (<i>N</i> = 16)	% male (<i>N</i> = 87)
Individual females	37.5	41.4
Children	6.3	20.7
Individual males	.0	12.6
Marital counseling	18.8	10.3
Family therapy	18.3	2.3

TABLE 4

Percentages of Female and Male Respondents Ranking Motives as Primary Motivation for Entering Private Practice

Motive	Sex	
	% female (<i>N</i> = 16)	% male (<i>N</i> = 93)
Freedom of hours	31.3	4.3
Do best work in this area	18.8	30.1
Could not get other attractive work	12.5	3.2
Service	12.5	7.5
High income	6.2	21.5
Do not like to work for others	6.2	14.0

also preferred therapists of the same sex, such a preference would remain unexpressed because there are so few female therapists.

ORIGINAL CAREER GOAL

Table 3 shows the items most frequently ranked first as an original career goal. Males ranked private practice in clinical psychology and clinical practice in an institution most often, and an academic career emphasizing teaching next. Most women, however, listed academic career with an emphasis on teaching as their original career choice, followed by private clinical practice and clinical work in an institution. The fact that large percentages of both sexes selected choices other than private practice as an original career goal could be because many clinicians either enter private practice when they are blocked in other endeavors, or private practice as an appealing profession is not apparent to the graduating student and is discovered later on.

MOTIVE FOR ENTERING PRIVATE PRACTICE

The item ranked first most often by males as a reason for entering private practice was ability to do best work in this area, while females chose private practice because of freedom of hours (see Table 4). This discrepancy may reflect women's larger home responsibilities, or women may not feel the same commitment to private practice as men. The latter fits with the finding that private practice was not an original career choice for many women. Males gave high income potential as the second most frequent response, and dislike of working for others was third. For women, other important considerations were doing best work in this area, unavailability of other attractive work, and desire to be of service.

Emphasis by males in this study on skill, achievement, and independence conforms to the traditional masculine stereotype (Kagan, 1964). Involvement of females in clinical practice appeared here to be due mainly to default, because they mentioned "freedom of hours" and "could not find other attractive work" as major reasons for going into private practice. Women, unlike men, also ranked

high the desire to be of service, which fits with the traditional female role.

Conclusion

Relatively few women were found to be in the private practice of psychology in cities in the Southeast. Data from the few who responded revealed several differences between them and their male colleagues, although these differences may not be reliable due to the small *N*. Women less often than men practiced full time, published, or showed consistent economic growth. Women devoted a greater proportion of their time than men to marital and family counseling, and less to working with children. No woman therapist reported adult males as primary clientele. Fewer women than men reported private practice as their original career goal. Finally, women seemed to be motivated to enter private practice because it afforded flexible working hours and a chance to be of service and because of lack of opportunity to find other attractive work. In contrast, men appeared to engage in private practice because it was the area in which they did their best work, had a high income potential, and afforded them independence. The sexes were alike in length of time in practice, training, awards, Diplomate status, sources of referrals, serving a large number of adult female clients, and, finally, in not holding private practice as their original career goal. The expectation that the female therapist might hold a preferred status in this area of psychology was *not* supported in this study.

Women as Job Changers

ELLEN KIMMEL *University of South Florida*¹

The purpose of the study reported here was to determine whether the statement "Women are a bad risk" is fact or myth with respect to women psychologists. One of the most frequent reasons for not recruiting or hiring women in general is that they are less likely than men to remain in their positions (Keyserling, 1968; U.S. Department of Labor, 1969). Yet studies comparing the mobility of women and men in many types of occupations yield conflicting results, the majority showing small differences. For professional workers, job-changing rates are relatively low, with some indication that the rates are somewhat higher for men than women (U.S. Department of Labor, 1969, 1972). The present survey focused on frequency of job change for men and women in psychology.

Method

DESCRIPTION OF SAMPLE

The sample consisted of 150 female and 150 male members of the Southeastern Psychological Association (SEPA) taken randomly from the 242 females and 1,076 males on the 1972 membership list.

SURVEY INSTRUMENT

The one-page questionnaire asked for (a) date of PhD or terminal degree, (b) area of specialization, and (c) a chronological listing of all jobs held since the terminal degree. Space was provided for all reasons for each change in employment. A covering letter on official SEPA stationery signed by the president asked each participant to provide the information requested. Neither the sex nor the name of the respondent was requested, the former because of the fear that individuals would be sensitized on the sex issue, and the latter to encourage honest and complete answers as to why they changed their jobs. Females were sent forms with elite type and males were sent forms with pica type.

DISTRIBUTION OF SURVEY

The survey was mailed out in the first week of November 1972. Because the response was good, it was not necessary to send a follow-up letter. Seventy-two females and 74 males responded.

Results and Discussion

Table 1 summarizes the primary data for males and females. The women's data are further broken down by terminal degree. This was not done for men because all but two had earned the doctorate. The areas of specialization within psychology were categorized into two general headings, "basic" or "applied." As might be expected, a greater number of the women (51, or 71%) received their training in an applied area than men (44, or 60%). There were no discernible differences between the sexes in areas of speciality within basic or applied fields. Table 1 also shows that women reported a total of 189 positions and men a total of 179. Jobs were categorized into three major types: private and public agencies (e.g., community mental health institutions, public school systems, or private corporations); self-employment (e.g., clinicians in private practice or industrial psychologists); and academic institutions (public or private universities, colleges or community colleges). Eighty-nine (47%) of the jobs held by women were with agencies, while 54 (30%) of the men's jobs were with agencies. Self-employment was negligible. Ninety-two (48%) of the females' jobs and 122 (68%) of the males' jobs were in academic institutions. Thus, the women were more often employed in agencies or self-employed than the men, especially women with MAs. The types of academic institutions in which women and men worked are also shown in Table 1. There were significant differences ($\chi^2 = 10.18$, $p < .02$) between the sexes, in that men more often had positions in universities than women, and women more often had jobs in small community colleges. This corroborates Joesting's finding (see pp. 520-523, this issue).

A mobility score was computed for each respondent by dividing the total number of jobs listed into the total number of years since the terminal degree. This results in a measure of job tenure in years per job. The scores ranged from .2 to 25.0. Table 1 shows that the females had a mean of 4.3 and the males a mean of 4.4 years per job. This difference was not significant ($t \approx 0$, $df = 144$). Women with MAs had larger average mobility

¹ More information may be obtained from Ellen Kimmel, University of South Florida, FAO 295, Tampa, Florida 33620.

* $p < .05$.** $p < .02$.

scores (were less mobile—5.2) than doctorates of either sex.

Table 2 compares the distributions of the actual number of jobs held by women and men. Although women held a greater number of jobs than men, the distributions of the two sexes did not differ ($\chi^2 < 1.0$). It is interesting to note that 18 females and 24 males were still in their first jobs, some for many years.

The question of whether mobility of psychologists is related to where they are employed required combining the data of both sexes, because the difference between the scores of women and men was small within each category of employment. Mobility of psychologists employed in agencies (3.4 years per job) was greater than that of persons in academic institutions (4.8 years).

Since mobility is known to be related to age (U.S. Department of Labor, 1969), the respondents were divided into groups within sex according to the age of terminal degree. This measure had to

be used because the actual age of the respondent was unknown. Ten years was arbitrarily taken to be the breaking point for defining "new" versus "old" degrees. The average mobility score was

TABLE 2

Distribution of Number of Jobs Held by Females and Males

Number of jobs	Females	Males
1	18	24
2	25	24
3	10	12
4	8	8
5	5	2
6	6	2
7	—	1
8	—	—
9	—	—
10	—	1
Total	72	74

computed separately for females and males with degrees 9 years or less and 10 years or more. Forty-five females and 42 males were in the "new" degree group (refer back to Table 1), with mobility scores of 2.6 and 2.8 years, respectively. Twenty-seven females and 32 males were in the old group, with mobility scores of 7.3 and 6.6, respectively.

Additional interesting information was obtained, incidental to the main question of mobility, that related to patterns of career advancement. With respect to the highest position achieved in their careers, the most notable difference between women and men was in the number who attained the rank of professor—8 women as opposed to 27 men. This is in keeping with national figures which showed that while only 50% of the women with doctorates for 20 years achieved the rank of full professor, the figure is 90% for men (Astin, 1969). Also, fewer women (13) held the rank of assistant professor than men (23). Fewer women than men reported administrative positions in academic institutions. Since a greater number of women held nonacademic positions than men, it was pleasing, but not surprising, to discover that a greater number of women than men held administrative positions in agencies.

The 222 reasons for changing jobs were analyzed into seven categories, shown at the bottom of Table 1. (The number of reasons was smaller than the total number of jobs described, because the first job reported by each respondent did not involve a change.) The first category, Professional Advancement, contained any reason describing a move resulting in an increment in salary, rank, prestige of the institution, and/or improved opportunities for professional growth. Only 36% of the reasons women gave, but 50% of the reasons men gave, were placed here. This difference was significant ($\chi^2 = 4.78$, $df = 1$, $p < .05$). National surveys of mobility (e.g., Brown, 1967) have shown that the majority of faculty moves result in advancement of some sort in the careers of the job changers. Thus, the data for men, but not women, resembled that obtained in national surveys. The other six major types of reasons are given in Table 1 in order of frequency of occurrence. Under Job Unsatisfactory, such reasons as "bored stiff," lack of opportunity to teach, unhappiness with the nature of the work, etc., were included. More men than women gave these sorts of reasons. Job Disappearance referred to grants that ended, fellowships that expired, or adjunct monies being reduced. Here, more women than men were affected. Spouse-Related reasons

included spouses changing jobs or disliking the area and consequently relocating. Such events forced the partner to change jobs. Eighteen women and only 1 man reported reasons of this sort. While this difference is quite large, 18 is only a small proportion (15%) of the 117 total reasons given by women for changing employment. The category Termination is self-explanatory, and no differences were apparent between women and men here. Personal reasons involved such things as poor health, dislike of climate or geographical area, divorce, or pregnancy. Ten percent of the females' and 3% of the males' reasons were placed in this category. The last category, Personality Conflict, is self-explanatory.

Women MAs were surprisingly similar to women PhDs in the reasons for changing employers. Women with better credentials, who were thus better able to change jobs to improve their status, did not report moving to advance professionally any more often than those presumably in a less favorable position to do so.

Conclusion

This study found that, despite some significant differences between women and men psychologists in the Southeast in training, type of employer, level of success achieved, and reasons for changing jobs, there was no significant difference in their job mobility. How then did the apparent myth that "women are a bad risk" start and what has maintained it? One possibility suggested by this study is that, though women are no more mobile than men, the reasons why they change jobs may be considered to be less valid, that is, less socially acceptable, thereby placing a kind of stigma on the move. The loss of a female psychologist from a department because of a spouse- or family-related event may lead to the development of a negative attitude about women as employees which would not occur from losing a male psychologist who moves to advance himself professionally. Thus, the same phenomenon (loss of an employee-colleague) is viewed in two quite different ways. Epstein's (1971) analysis of the obstacles women encounter as professionals supports this idea. To the extent that women deviate from the norm of what a "good" professional does (e.g., changes jobs for professional advancement), they are seen as less committed and otherwise negatively regarded by their male peers. Regardless of how the myth got started, what must be emphasized

at this point is that it was not supported by the data collected in this study. Chairs and directors in psychology may hire women with the same degree of confidence with which they hire men with respect to the expected time that women will remain in their jobs.

SEPA's Affirmative Action

It may be concluded that women in psychology in the Southeast, except, in certain respects, women doctoral students, hold a "minority" status. In light of the evidence pointing to this conclusion, some affirmative action activities that are being conducted by SEPA and the Status of Women group are described here. Having studied the problem empirically, members of the Commission felt it was appropriate to act and asked to be reappointed and given a small budget in order to do so. First, the Commission asked the members of SEPA to endorse a formal resolution calling for the improvement of the status of women in the organization itself.¹

Second, at the request of the Commission,

¹The resolution, which was passed by SEPA in April 1974, reads as follows:

Resolve that the Southeastern Psychological Association support affirmative action for women in psychology in the Southeast in the next year by making special efforts to recruit women members, to include women on committees and in positions of leadership in SEPA, and to nominate or otherwise promote women in the Southeast for positions of responsibility in psychology at the national level.

SEPA's Executive Committee appointed Judith Worrell to chair a committee to select the winner of a Student Research Paper Award (\$100 prize). Students of either sex may compete. The topic of the paper must be related to the purpose of APA's Division 35 (Psychology of Women), namely, to "promote the research and study of women, including both the biological and sociocultural determinants of behavior and to encourage the integration of this information about women with the current psychology of knowledge and beliefs in order to apply the gained knowledge to the society and its institutions." Program space was reserved at the 1974 annual meeting of SEPA for the reading of the winning paper.

Third, the most ambitious project now underway is the Commission's Visiting Woman Program. The proposal for this was first introduced by its originator, LaMyra Davis, at SEPA's 1973 annual meeting. Brochures describing the program have been sent to approximately 500 psychology departments along with information copies to the presidents of their colleges or universities. The brochures contain information (names, addresses, titles of colloquia) about women psychologists who have vol-

unteered (for expenses only) to serve as a woman visitor. Each department has been encouraged to participate by inviting at least one volunteer to its campus to deliver a colloquium address to students and faculty and to talk informally with women (only) students at some other time in the visit. The purpose of the program is to provide additional role models for women students, where few are currently available (see the Joesting and Kimmel articles this issue), who will encourage talented women to enter or continue in the pursuit of a career in the field of psychology. The Commission also hopes for an atmosphere effect within departments that "shows they care" by electing to engage in this affirmative action program. Such a spin-off benefit might elevate women's motivation and, consequently, performance.

Women who visit will collect data for the Com-

mission and, along with students and department chairs, contribute to the evaluation of the short-term impact of the visit. A formal report on the Visiting Woman Program was presented to SEPA. Other anticipated benefits of the Visiting Woman Program include such things as boosts in the careers of the women who make the visit (few women currently receive invitations to deliver colloquia), stimulation of new ideas about psychology and/or affirmative action, and development of new relationships between the women faculty and students within the department which was visited.²

Research and Relevance

A Survey of Graduate Students and Faculty in Psychology

MARK W. LIPSEY *Claremont Graduate School*¹

The perspicacious listener can hear the more-than-faint rumblings of approaching breakthrough [McGuire, 1969, p. 38].

A revolution of some sort is developing in psychology [Schultz, 1970, p. 394].

There seems little doubt that experimental psychology is ripe for a revolution . . . [Palermo, 1971, p. 155].

Psychology is in a state of crisis [Deese, 1972, p. 1].

Something is happening in psychology. This not especially original observation echoes the conclusions of such diverse psychologists as those cited above and others too numerous to mention. But in spite of the fact that many psychologists agree that *something* is happening, there is remarkably little evidence available to indicate just *what* is happening. Results of a survey of faculty and graduate students conducted during 1970-1971 by a group of graduate students at Johns Hopkins University make, we think, at least a modest contribution to understanding the changing face of contemporary psychology and provide some basis for speculating about its future. The items in that questionnaire dealt primarily with issues in psychology, graduate education, professional journals, and general communication. All of the full-time graduate students enrolled in a representative sample of 106 graduate departments of psychology received the survey, and it was returned by 2,340 graduate students² in 95 of the sampled depart-

ments—a return rate estimated at 50%.³ A parallel form of the survey was also sent to a random sample of 500 faculty members in graduate departments selected from the APA *Directory*.⁴ The faculty returned 368 (74%) of those questionnaires.

Issues in Psychology

The major issues in psychology could be established, at least in broad outline, from the responses to an open-ended item asking, "What do you feel is the single most important issue confronting psychology today?" The write-in responses to that item were coded into a number of general categories, each with finer subdivisions.⁵ A summary of the results of that process appears in Table 1. Though considerable diversity was present, as might be expected from such a vague, open-ended item, three broad areas of concern stood out. These have been labeled *relevance, research and theory, and therapy and humanism*.

¹ This article is a summary version of a considerably larger report (Lipsey, 1973) which is available from the Journal Supplement Abstract Service, APA.

The student survey was conducted under contract to the Office of Communications, APA, and supported by National Science Foundation Grants 772 and 901. Coding and analysis of the faculty survey were supported by National Institutes of Health Grant 1 RO3 MH19648-01 MSM.

Requests for reprints should be sent to Mark W. Lipsey, Department of Psychology, Claremont Graduate School, Claremont, California 91711.

² The number for the analyses reported here was 2,140; 200 questionnaires were omitted from those analyses.

³ For further information regarding the study and its design, sampling, bias, etc., see SoGSIP Study Group (1971) and Lipsey (1973).

⁴ The faculty survey was done by William Garvey of the Johns Hopkins University Center for Research in Scientific Communication. The faculty and student surveys were analyzed together to allow faculty-student comparisons.

⁵ The original coder agreed with himself 80% of the time on the broad categorization and 60% of the time on the subdivisions when recoding a sample of the responses.

TABLE 1

The Most Important Issue Confronting Psychology

^b Mean on a 7-point scale from very well (1) to not at all (7).

RELEVANCE

About half of the graduate students and nearly the same proportion of faculty identified some aspect of relevance as the most important issue confronting contemporary psychology. Most of the responses cited relevance in a general way—relevance to social problems, the “real world,” and so forth. Many, however, stressed not just relevance but the *direct* application of research findings; this group included 12% of the students, though only 5% of the faculty. Closely related was the number of students (11%) and faculty (9%) who listed the need to develop and apply psychological research to *specific* problems, for example, race, environment, militarism. In addition, a number of graduate students (5%) and even more faculty (12%) identified relevance as the most important issue, while explicitly withholding their own endorsement or otherwise expressing caution or apprehension over the cry for relevance. Feelings of concern and confusion about just what psychology should be doing were more broadly represented in the category labeled *identity; goals*, which included about 7% of the students and 8% of the faculty.

The questionnaire also included some yes-no items specifically dealing with academic psychology's role in the solution of social problems. Ninety-two percent of the students and 83% of the faculty responded, “Yes . . . academic psychology *should* be concerned with contemporary social problems.” Ninety percent of the students, however, and 79% of the faculty said they did *not* think that academic psychology was making a significant contribution to the needed solutions. There was a rather striking gap between the “is” and the “ought” for academic psychology in the minds of graduate students and faculty. The fault could lie, we reasoned, either with academic psychology, which might not be perceived as producing useful knowledge, or with those in the society at large who were not making full use of the available knowledge. Fifty-one percent of the students and 52% of the faculty felt that “academic psychology does not yet have much knowledge relevant to social problems . . .” but, optimistically, “might develop such knowledge if it tried.” Thirty-seven percent of the graduates and 25% of the faculty

TABLE 2

Factor Loadings for Thirteen "Issue" Items

Item	Factor 1 (social concern)		Factor 2 (experimentalism)	
	Student	Faculty	Student	Faculty
The knowledge and methods of experimental psychology have developed to the point where fundamental problems related to behavior are potentially solvable.	.09	.07	.48	.55
An increasing awareness of man's capacity for self-actualization could be psychology's greatest contribution to society.	.44	.51	-.19	-.20
Laboratory experimentation, however slow and painful, is still the most adequate tool psychology possesses for increasing its useful knowledge.	-.36	-.39	.50	.54
Psychology may be able to study value judgments, but it must be careful not to make them.	-.20	-.42	.06	.06
For all its efforts to study learning, psychology has not provided much useful knowledge to the classroom teacher.	.00	-.05	-.38	-.51
The operational definitions of the laboratory experiment are rarely related in a meaningful way to what happens in ordinary situations.	.19	.24	-.58	-.58
Psychology should be leading the search for new means of promoting human welfare.	.69	.74	-.01	-.08
Psychology needs to replace much laboratory research with careful studies of ordinary behavior in natural settings.	.42	.43	-.43	-.52
Psychologists study people as objects when they should be studying them as people.	.39	.59	-.47	-.43
Research psychologists should not be held responsible for the use society makes of their findings.	-.35	-.39	.10	.07
Psychological research mimics only the surface features of research in the physical sciences.	.10	.17	-.41	-.44
Psychologists have an obligation to demonstrate the worth of their endeavors to the society which supports them.	.36	.39	-.05	-.06
Psychologists may be obligated to communicate what they know, but they have no special obligation to solve social problems.	-.68	-.76	-.05	.05

Note. Minres factor analysis with varimax rotation. Five items were excluded from this table; they showed no relationship to the two major factors. Separate factor analyses were done on the student and on the faculty data.

thought the problem was that "academic psychology has produced much relevant knowledge, but it is not being fully applied to real world problems." Clearly, then, there was a great deal of dissatisfaction with what psychology was doing about social problems, and most students and faculty felt that the blame belonged within psychology itself.

RESEARCH AND THEORY

Responses judged as dealing with the general theme of research and theory were given with second-most frequency by both students (12%) and faculty (19%) as "the most important issue" confronting psychology. The most frequent type of comment identified psychology's central task as understanding behavior or human nature. Two other high-frequency responses in the research and theory category were the need for better theory, or a unifying theoretical structure, and the need for improved research methods and skills. There seemed to be in these responses a feeling that the appropriate action for psychology would be to get

on with the research that would enable it to meet its original goal, the understanding of behavior, and, perhaps, a recognition that the goal must be reemphasized because psychology's performance to date has not been very dramatic.

THERAPY AND HUMANISM

Eleven percent of the graduate students, but only 3% of the faculty, named issues judged in the therapy and humanism category as the most important issue confronting psychology. The student-faculty difference was undoubtedly due to the greater proportion of graduate students interested in clinical psychology than graduate faculty. The students in this category most frequently mentioned contribution to individual fulfillment or, as one said, "how to provide the conditions for human development." The faculty who gave responses in the therapy and humanism category were most likely to express general concern for the human condition and psychology's conception of the nature of the human organism. Of about equal fre-

quency among students and faculty were responses focusing on the ethics of the research and the behavior of psychologists.

Experimentalism and Social Concern

In addition to the open-ended issue item, the survey questionnaire included a variety of statements regarding psychological methodology and social relevance to which students and faculty could respond on 7-point scales ranging from agree (1) to disagree (7). These items explored in a little more detail two of the major areas of concern that were identified in the open-ended responses of the most important issue confronting psychology. Those two issues, the discipline's appropriate role in the "promotion of human welfare" and the serviceability of the experimental tradition, were reflected in two of the factors that emerged from factor analysis of the items presented in Table 2.

Factor 1, labeled *social concern*, combined concern for promoting human welfare, a sense of special obligation to solve social problems, belief in man's capacity for self-fulfillment, need to demonstrate psychology's value to society, and a feeling of responsibility for the use society makes of psychological findings. Associated with Factor 2, labeled *experimentalism*, were an affirmation of confidence in the problem-solving potential of experimental psychology and laboratory methodology, support of operationism, satisfaction with psychology's past efforts to study learning, and disagreement that the discipline only mimics the physical sciences.

In order to examine more closely the students and faculty who took one or another of the four possible positions on these two issues, each person in the sample was assigned two factor scores⁶—one to represent his position on the social concern factor and another to represent his position on the experimentalism factor. Since 4 was the midpoint on the 7-point agree-disagree scale that accompanied each item, the factor score that would correspond to a uniform response of 4 on all of the items represented in the factor was designated as the neutral point on each factor. Using the two factor scores and the designated neutral points,

each individual was classified into one of the four quadrants formed by the orthogonal factors.

It was possible to give a very general description of the inhabitants of each quadrant by examining the proportion of students and faculty in each, their predominant areas of interest in psychology, and their response to an item asking which person in psychology or a related area had produced the work they most respected. A special word needs to be said about this last item. The diversity of responses was so great that we found it convenient to collapse them into 12 categories of researchers who seemed to us to do more or less similar work. These 12 categories were thus inexact, but suggestive, we think, of different perspectives on psychological research. Figure 1 identifies the composition of each quadrant in terms of the general items.

In the pro-experimental, anti-social-concern quadrant there was a predominance of students and faculty with interests in such areas as comparative psychology, learning, and physiological psychology. They mentioned favorably the work of psychologists such as Estes, Pavlov, and Neal Miller. The attitudes that put them in that quadrant, of course, were supportive of experimental psychology and reflected the "basic" scientist's unconcern for immediately applicable research results—a pattern that marked them as basic researchers—and we have applied that label to their quadrant. These basic researchers comprised the second largest quadrant among faculty members with 28%, but among the students it was the least popular position; and the difference between the student proportion and the faculty proportion was larger there than for any other quadrant.

The mirror images of the basic researchers, in terms of their attitudes, were the anti-experimental, pro-social-concern citizens of the second quadrant. That quadrant was composed primarily of clinical psychologists along with some social-personality and applied psychologists. Their strong pro-social-concern stance and their heavy citation of such psychologists as Carl Rogers, as well as Freud and Allport, have led us to label this quadrant *humanist-activists*. The second largest discrepancy between proportion of faculty and proportion of students in a quadrant occurred here, but this time the direction was reversed. Students were nearly twice as likely as faculty to hold the attitudes of the humanist-activists, and that remained true even when the predominant clinical psychologists were separated out.

⁶ The factor scores were calculated by Bartlett's procedure. The factor analysis of student and faculty responses agreed so closely that it was possible to use the same set of weights for calculating both the student and the faculty factor scores.

PRO-SOCIAL CONCERN				
HUMANIST-ACTIVISTS			SOCIAL ENGINEERS	
	Faculty	Students	Faculty	Students
% of total	18%	35%	34%	43%
% without clinical	15%	31%	32%	43%

ANTI-SOCIAL CONCERN				

Figure 1. Size and general composition of the factor quadrants. (The relationship between each of the items in this table and the four quadrants was statistically significant at the .05 level at least by chi-square tests. The percentages refer to the proportion of the category who are in each quadrant; for example, clinical [35%] indicates that 35% of all the clinicians were in that quadrant; Rogers [60%] indicates that 60% of all those who cited a name in the Rogers category were in that quadrant. Nothing was listed as distinctive of a quadrant unless the percentage of respondents exceeded the total percentage in the quadrant by at least one fourth again.)

The largest quadrant for both faculty and graduate students was that representing pro-experimental and pro-social-concern attitudes. Because of their defining attitudes, the overrepresentation of those with applied interests (educational-developmental, general applied), and especially because of the heavy mention of B. F. Skinner as the psychologist of choice,⁷ this quadrant has been labeled *social engineers*. Even without the clinical psychologist, this quadrant was still the largest among students, and, among faculty, as large as its nearest competitor, basic researchers.

Those in the final quadrant combined anti-experimentalism with anti-social-concern in a double negative. Their negativism contrasted sharply with the comparative zealotry of those in the other quadrants, all of whom were "pro" about something. We have, therefore, named them *Mugs* after

⁷ Skinner alone received about 13% of both the student and faculty responses to the most-respected-person item, outdistancing his nearest competitors by margins of two to one or more. Half or more of all the responses in the Skinner category came from those in the social engineers quadrant.

Not contributing; lacks relevant findings.	79	63	34	41	69	67	45	43
Not contributing; problems are impossibly complex.	1	3	0	1	8	7	6	3

Note. The relationship between each of the items in this table and the four quadrants was statistically significant at the .05 level at least using chi-square tests. The percentages in each quadrant refer to the proportion of those in that quadrant giving a particular response.

^a Percentage marking the extremes (1 and 2 or 6 and 7) on 7-point rating scales.

the "scientific conservationists" described by Nigel Calder (1969) in *Technopolis* as "disinclined to believe anything." This quadrant was the next to smallest among both faculty and students, though it contained a greater proportion of faculty than of students. Those faculty and students interested in perception, cognition, and quantitative psychology were overrepresented in this quadrant, and they frequently mentioned psychologists such as George Miller, Piaget, and Meehl as important contributors.

ISSUES

The position of each group on the major issues in psychology, of course, was pretty much given by the factor definition of their quadrant—pro- or anti-social-concern, pro- or anti-experimentalism. Table 3, however, shows that more information about these positions may be gained by examining the responses to the other issue-oriented items.

Among faculty, social relevance was identified as the most important issue confronting psychology

by fewer basic researchers than any other subgroup, and the proportion was next to smallest for the student basic researchers. The basic researchers were also most likely to mention apprehension over demands for relevance or urge that a balance be preserved between basic and "relevant" research. The most frequent citation of relevance among the faculty came from the humanist-activists; among the students, from the social engineers.

A sizable majority of those in every quadrant felt that "academic psychology should be concerned with contemporary social problems," though fewer of those in the anti-social-concern groups felt that concern with social problems was legitimate. The majority of those in each quadrant, however, also believed that academic psychology was *not* contributing to the solution of contemporary social problems. Most of the Mugs and humanist-activists felt that the reason for this failure was that "academic psychology does not yet have much knowledge relevant to social problems," and the largest proportion of basic researchers agreed. The

Note. The relationship between each of the items in this table and the four quadrants was statistically significant at the .05 level at least using chi-square tests. The percentages in each quadrant refer to the proportion of those in that quadrant giving a particular response.

^a These percentages refer to those marking the extremes on a 7-point scale: 1 or 2 for desirable, 6 or 7 for undesirable.

largest number of social engineers, however, believed that "academic psychology has produced much relevant knowledge, but it is not being fully applied to 'real world' problems." And a larger number of the social engineering faculty than in any other quadrant thought that academic psychology already was "contributing significantly" to the solution of social problems.

Not all mention of significant issues in contemporary psychology, of course, emphasized social relevance. In fact, the most frequently mentioned issues among Mugs and basic researchers dealt with aspects of psychological research and theory. Such essentially scientific concerns, however, did not indicate that the Mugs and basic researchers were untouched by the difficulties the discipline is experiencing. Each of these groups identified more issues in the category involving the identity and

goals of the discipline than the humanist-activists and social engineers combined.

GRADUATE TRAINING

Attitudes toward social concern and experimentalism were also related to the graduate student's satisfaction with his department, his career plans, and both the student and faculty description of the ideal graduate department, as is shown in Table 4.

The most frequently offered graduate degree, according to the APA publication *Graduate Study in Psychology: 1972-73*, is in experimental psychology. If the typical department is organized around the needs and values of the basic researcher in psychology, we might expect the student basic researchers to be the most satisfied with their graduate training. That was indeed the case. The students were asked to rate their reaction to graduate

TABLE 5

Response to Research and Publication Items by Those in Each of the Factor Quadrants

Item	Pro-social concern				Anti-social concern

Those successful if theoretical article attempted	82%	61%	93%	48%	66%	50%	88%	56%

Note. Except as noted, the relationship between each of the items in this table and the four quadrants was statistically significant at the .05 level at least using chi-square tests. The percentages in each quadrant refer to the proportion of those in that quadrant giving a particular response.

* The responses to these items were not related to the factor quadrants at a significant level.

school relative to their expectations on a 7-point scale from extremely pleased (1) to big disappointment (7). The mean rating indicated greater satisfaction for students in the basic research quadrant than for students in any other quadrant. The humanist-activist students, most discrepant from the values of the basic researchers, were the least happy with their graduate school experience. The Mug and social engineering students, each agreeing with the basic researchers on one factor and disagreeing on the other, showed similar, intermediate levels of satisfaction with their graduate departments.

Differences also emerged in the type of graduate department thought ideal by the students and faculty in each quadrant. Various graduate school descriptions were rated on a 7-point scale, and we have translated the results into the percentage who gave a very desirable rating (1 or 2) and the percentage who gave a very undesirable rating (6 or 7) in order to facilitate comparison. All groups except the humanist-activist students found as most desirable a graduate department composed of "teachers and students involved in scholarly investigation and broad education in their field of interest" with the greatest endorsement coming from the faculty basic researchers. The humanist-activist students thought the most desirable department was "a place for students to gain a deeper

understanding of themselves and of their fellow man," and a large number of their faculty also found that description highly attractive.

RESEARCH AND PUBLICATION

The overwhelming majority of both students and faculty in all the quadrants reported that they had been doing research (see Table 5). Though the proportion who were doing research did not vary as much as 10% from quadrant to quadrant, the proportion who were personally satisfied with their own research varied much more widely. A majority of the basic researchers who were engaged in research reported being very satisfied with it and few reported great dissatisfaction. The humanist-activists, on the other hand, were considerably less pleased with their research progress: Fewer than half reported great satisfaction and more expressed great dissatisfaction than in any other quadrant. The Mugs, who, unlike many of the humanist-activists, brought a basic science orientation to their research, were surprisingly similar to the humanist-activists in their relatively moderate research satisfaction. The social engineers, though more satisfied than the Mugs, resembled them more than they did the basic researchers. Apparently, the difficulties and frustrations of academic research increase the more remote the researcher is from the attitudes and values of the basic researchers.

TABLE 6

Response to Journal/Communication Items by Those in Each of the Factor Quadrants

Item	Pro-social concern				Anti-social concern			
	Anti-experimentalism		Pro-experimentalism		Anti-experimentalism		Pro-experimentalism	
	Humanist-activists		Social engineers		Mugs		Basic researchers

Editing	10%	16%	14%	20%	33%	20%	37%	26%
Few biases/more un-orthodoxy	39%	27%	26%	17%	18%	16%	9%	6%

Note. The relationship between each of the items in this table and the four quadrants was statistically significant at the .05 level at least using chi-square tests. The percentages in each quadrant refer to the proportion of those in that quadrant giving a particular response.

Academic research usually results in the publication of journal articles, so we also took a look at the lifetime publication experience of those in the different quadrants. The basic researchers might be expected to be the most frequently published group and that was true for student basic researchers. The basic research faculty, however, averaged slightly fewer journal publications per person than the Mug faculty. Humanist-activists, as might be anticipated given their clinical orientation, were the least published group, and the social engineers were more similar to them than to Mugs or basic researchers. There were fewer persons in some of these quadrants who were engaged in research than in others, of course, but adjusting the publication frequency according to the number of active researchers did not alter the rank order of the results.

There were no significant differences among the quadrants in the percentage who reported that they had had at least one manuscript rejected by a journal nor in the average number of rejections reported by those with rejections. Because the pub-

lication frequency varied, however, these rejection figures indicated that on a per publication basis humanist-activists and social engineers were somewhat more likely to have their manuscripts rejected by the journals, while Mugs and basic researchers were less likely to have this happen.

Respondents were also asked if they had ever attempted to publish a "theoretical article." There were no significant differences among the quadrants in the number reporting that they had attempted a theoretical article, but there were marked differences in the success they reported. Of those attempting such articles, the social engineering and basic research faculty were the most successful, with the humanist-activist faculty not too far off their pace. The Mugs, however, were notably less successful, a rather strange finding considering that their overall publication record was the best of the four groups.

JOURNALS AND COMMUNICATION

Attitudes on the social concern and experimentalism issues were also strongly related to utilization

of the various communication modes in psychology and to satisfaction with the professional journals, as Table 6 shows. Faculty and graduate students were asked to check from a list of information sources those from which they received "valuable ideas" relevant to their work and interests. Those in each of the four quadrants showed a different pattern of dependence on the various information sources. The professional journals were the most frequently cited by all groups except humanist-activist students, but the response was greatest for social engineers and basic researchers. In place of the journals, many Mugs and humanist-activists relied for useful information on nonprofessional periodicals and nonfiction books other than texts; they cited these sources about twice as frequently as their pro-experimental counterparts.

Many of the most prestigious of the professional journals, of course, are directed toward the basic researcher. It was not surprising, therefore, that satisfaction with the journals was highest among basic researchers and least among those most different from basic researchers. On an item requesting a rating of satisfaction with the "editorial selection and contents of the journals," basic researchers were found to be the most satisfied, humanist-activists were the least satisfied, and Mugs and social engineers were in between.

We can understand each group's perception of the professional journals better by examining the write-in responses they made when asked to suggest a way of improving the journals. We have collapsed these write-in responses into three large, general categories: (a) organization/writing, (b) tighter editing, and (c) fewer biases/more unorthodoxy. Most of the suggestions for improving the journals fell into the organization/writing category, citing, for the most part, the need for better or clearer writing and, especially, for more interesting writing. The Mugs and basic researchers, however, were particularly desirous of more restrictive editing, though about twice as many Mugs came out for the opposite—more tolerant editing allowing more unorthodox articles. Humanist-activists and social engineers were also disproportionately interested in looser editorial criteria, especially those that would allow publication of more socially relevant and applied research.

Faculty to Student Trends

We have seen that psychologists are divided over the issues of social relevance and the serviceability

of the experimental tradition and, moreover, that there were faculty-student differences on these issues: 78% of the students, but only 52% of the faculty, were in the pro-social-concern quadrants and 47% of the students were in the anti-experimental quadrants with only 38% of the faculty. By further subdividing the faculty and student groups according to the number of years experience they have had in psychology, it was possible to get a cross-sectional look at the changes taking place in psychology. We assume that if the students' attitudes differ from those of the faculty and if those attitudes do not change dramatically as they become faculty, then the disciplinary consensus will change in the direction of those attitudes.

Notice, however, that it is quite misleading to compare the faculty at graduate schools to *all* the graduate students in psychology. As academic researchers and teachers, the faculty necessarily embodied many attitudes inappropriate to the large numbers of students who were not training to become academicians themselves. In the remainder of this article, therefore, we will narrow our focus to *academic* psychology and examine only those students who planned an academic career.

THE SOCIAL CONCERN FACTOR

Comparison of the factor scores on the social concern factor for five academic student and faculty groups⁸ revealed a generally decreasing function relating social concern to experience in psychology (see Table 7). The midcareer faculty expressed a lack of enthusiasm for the promoting-human-welfare, solving-social-problems model of psychology that distinguished them from all the other groups. Indeed, their mean score shaded over into the area where they were for the most part disagreeing with the positively worded items that comprised that factor and agreeing with the negative ones. New students, older students, and new faculty lived up to their stereotype and showed the most desire for a "relevant" psychology, with new students and older

⁸ The following subdivisions were used: new students ($N = 619$): first- and second-year doctoral candidates planning an academic career; older students ($N = 625$): third- and last-year doctoral candidates planning an academic career; new faculty ($N = 65$): faculty members in a graduate department who received their doctorate between 1966 and 1968, inclusive; midcareer faculty ($N = 163$): faculty members in a graduate department who received their doctorate between 1957 and 1965, inclusive; posttenure faculty ($N = 120$): faculty members in a graduate department who received their doctorate during or before 1956.

TABLE 7

Analysis of Variance of Social Concern and Experimentalism Scores

	New students	Older students	New faculty	Midcareer faculty	Posttenure faculty
Social concern scores					
Group mean ^a	50.90	50.10	47.62	42.94	43.60
Experimentalism scores					
Group mean ^b	45.16	43.77	46.18	45.85	43.24

Note. Higher social concern scores indicate a more pro-social-concern attitude; higher experimentalism scores indicate a more pro-experimentalism attitude. The neutral point for the social concern scale was 43.33; for the experimentalism scale, 42.50.

^a Between ANOVA: $MS = 3,151.49$, $F = 16.21$, $df = 4$, $p < .01$. Within ANOVA: $MS = 194.34$, $df = 1,587$.

^b Between ANOVA: $MS = 313.83$, $F = 2.58$, $df = 4$, $p < .05$. Within ANOVA: $MS = 121.69$, $df = 1,587$.

students very similar and more eager than the new faculty. The real surprise was the relative moderation of the posttenure faculty. That group contained the most experienced and influential psychologists in the sample, and though their concern that the discipline relate to the larger society was very similar to that of the midcareer faculty, it was nevertheless greater than would be expected by extrapolating the trend of the other four groups.

The same gradient that characterized the overall groups also described, more or less, the pattern of scores within major areas of specialization in psychology. To see this, each of the student and faculty groups was subdivided into four general areas labeled *experimental*, *cognitive*, *social*, and *clinical*.⁹ Since the numbers for the faculty subgroups were then rather small, the faculty and student subgroups were combined and the faculty-student difference on the factor scores was determined within each area of interest group (see Table 8).

The most dramatic difference emerging from the breakdown by area of interest, however, was between those in experimental or cognitive areas and those in social or clinical areas. The factor scores for experimental and cognitive faculty were below

⁹ The label *experimental* covers general experimental, motivation, learning, operant, physiological, animal, comparative, mathematical, and quantitative; *cognitive* covers perception, developmental, psycholinguistics, and cognitive; *social* covers social, personality, personnel, industrial, applied, educational and school; *clinical* covers clinical, behavior modification, and community.

the neutral point, that is, in the range where they were for the most part disagreeing with the social concern items that comprised that factor. The cognitive and experimental students were clearly on the pro-social-concern side along with all the social and clinical groups. In terms of the polarization across the neutral point on this issue, it seems to be the experimental and cognitive faculty versus everyone else including their own students.

THE EXPERIMENTALISM FACTOR

The pattern of means across the academic student and faculty groups on the experimentalism factor was somewhat similar to that which appeared on the social concern factor, though the differences were not nearly so marked (see Table 7). The midcareer faculty, who were the least concerned about producing socially useful research, were the second most accepting of the experimental tradition. The students and posttenure faculty differed from them by being less imbued with the experimental values, and the new faculty, in this case, were the most experimental. The means for all groups fell above the neutral point on the scale; thus, none of the groups was really *anti-experimental*; on the average they agreed at least slightly with pro-experimental items and disagreed at least slightly with anti-experimental items.

Collapsing the subgroups of the students and of the faculty and subdividing by areas of specialization produced no statistically significant student-

TABLE 8

Comparison of Student and Faculty Factor Scores for Areas of Specialization

TABLE 9

*Faculty and Student Rankings of
Graduate School Descriptions*

Description	Accuracy ranking	Desirability ranking
Professional training stressing practical skills and background study in preparation for a career.	1	3
Teachers and students involved in scholarly investigation and broad education in their field of interest.	2	1
A research institution where junior and senior investigators are free to work on problems of basic science.	3	2
A place for students to gain a deeper understanding of themselves and of their fellow man.	4	4
A pool of experts and trainees to which administrators and citizens can appeal for help with social problems.	5	5

Note. Rankings are based on the rank order of the mean desirability and accuracy ratings made for each item; ratings were made on 7-point scales from desirable to undesirable or from accurate to inaccurate.

faculty differences at all on the experimentalism factor score (see Table 8). This was largely due to the moderation of the posttenure faculty, but nevertheless indicated that within no specialty area is there a really strong faculty to academic student trend away from the support of experimentalism in spite of the very slight trend overall. Only the social students fell below the neutral point on the scale and could thus be called anti-experimental (though ever so slightly); the others were just more or less pro-experimental.

The experimentalism and social concern factors were, of course, independent, yet the pattern of differences across the faculty and academic student groups were similar: Where a lot of pro-social-concern sentiment existed, there generally coexisted somewhat less pro-experimental sentiment. It seems that the criticisms that have been leveled against experimental psychology, of which irrelevance is one, have had a slight chilling effect on the vigor with which that tradition is defended, especially among students and, to a surprising degree, posttenure faculty. The overall trend, from faculty to academic students, lends support to the view that the discipline is undergoing some change in its attitudes toward experimentalism as well as toward social concern, although at a considerably slower rate.

POSSIBLE EFFECTS ON GRADUATE DEPARTMENTS

The discussion of faculty to student trends has been restricted to those students who were planning careers in academic psychology, because only that group was truly comparable to the faculty, all of whom were academicians. Academic psychology, by and large, means graduate departments in psychology, and at this point it seems pertinent to wonder if the apparent trends that have been identified toward increased concern for social problems and the slight weakening of the research values of the experimental tradition portend any significant changes in the structure and operation of graduate departments.

The similar and generally pro-experimental attitudes of most of the faculty and student groups indicated that high value was put on the kind of research associated with an academic setting in spite of the skepticism expressed by many psychologists. This interpretation was corroborated by more direct evidence from the questionnaire item that dealt with the accuracy and desirability of various brief descriptions of graduate departments. Table 9 presents the order in which the various descriptions pertinent to this discussion were ranked by the faculty and graduate students planning academic careers.

The typical graduate department was thought to be most accurately portrayed as a place for "professional training," "scholarly investigation and broad education," and "work on problems of basic science." The descriptions dealing with humanistic concerns ("deeper understanding") and social involvement ("help with social problems") were seen as the least accurate descriptors.

The ranking that indicates which descriptions were seen as most *desirable* or highly valued was almost identical to that for the accuracy of the description. Most significantly, the descriptions dealing with "scholarly investigation" and "basic science" were still ranked at the top, while those for "deeper understanding" and "help with social problems" were still ranked lowest.

Clearly, then, neither faculty nor academic students were prepared to desert the "ivory tower"—scholarly investigation and broad education in a basic science research institution—in favor of either active involvement with social problems outside the department or the personal development of the students within the department.

This article was introduced with the not so original claim that something was happening in psychology. The findings that have been presented indicate that a large part of that "something" involves not so much workaday research and theory but "metapsychology" or, if you will, "ideology"—the values and attitudes of the psychologist regarding his work and his discipline. The issue that generated the most heat was social relevance, the demand that psychology involve itself constructively in the widespread social problems that beset society. A large majority of both students and faculty felt that the discipline should be contributing to the solution of social problems, but an equally large majority felt that at present it was making no important contribution. Most significant were the large faculty-student differences on this social relevance issue with a smooth gradient from mid-career faculty, the least responsive, to new graduate students, the most responsive. If the students and young faculty retain their present attitudes as they mature in the discipline, the relevance cause will be sailing under an increasingly high wind for many years to come.

The position we associated with the basic researcher—defined by both disinterest in social problems and commitment to experimental methodology—constitutes the dominant tradition which is under attack and susceptible to change. Even its methodology, seen by many as the *sine qua non* of science, receives less support from the upcoming generations of psychologists than among most of its current faculty practitioners. There does not appear to be a single, unified "revolution" against the experimental tradition, however. Instead, our data seemed to show at least three separate countermovements, each divided from the others on matters of fundamental importance to its followers. We labeled these three movements humanist-activists, social engineers, and Mugs.

The students seemed to be attracted primarily to the ranks of the humanist-activists and the social engineers. Though this makes it appear that it will be one or both of these positions that becomes dominant in academic psychology, we noted that both groups showed applied interests—clinical, educational, etc.—and fewer of their students were planning academic careers. Furthermore, faculty and student ratings of their preferences for a graduate department showed that the department offering "help with social problems" was the least

preferred of all the possibilities, while "scholarly investigation" and a "research institution" were highly valued. There thus seemed to be little support among academicians and potential academicians for a sudden transformation of the present-day graduate department in spite of their considerable sympathy with the cry for relevance. With increasing numbers of students attracted to their ranks, however, the humanist-activists and social engineers have the potential for making a significant social contribution in those areas in which they involve themselves. Indeed, it may be on their shoulders that the charge to make psychology relevant rests most heavily.

The unmistakable academicians of our three countermovements were the Mugs. Their attitudes were compatible with academic values and their rate of publication, an index of basic research interests, was as great as that of the basic researchers. Their cognitive and methodological interests could conceivably result in a choice of problems of broad enough significance to have the "relevance" that comes from asking important questions. Consider, for example, the influence Piaget's developmental psychology already has had on education and the potential inherent in Campbell's (1971) "experimenting society." Thus, the insurgence of the Mugs, because it dovetails both with academic values and, potentially at least, with the demand for social relevance, seems to be the countermovement most likely to succeed within academic psychology.

The Two-Year College Instructor

A Profile

J. RUSSELL NAZZARO *American Psychological Association*¹

There was a time in the not too distant past when teachers of psychology were thought to be people who worked in four-year colleges and graduate schools. In recent years, however, psychology courses have also become popular offerings at the high school and two-year college levels. In response to this growth, the American Psychological Association has begun to examine how it might expand and improve its services to a new population of psychology teachers. Acting on a recommendation from the Ad hoc Committee on the Two-Year College, the APA Educational Affairs Office conducted a survey during the spring of 1973 to gather information about the two-year college teacher and to explore how the national organization might serve these teachers' needs.

Since there existed no national roster of two-year college psychology instructors, a search for names was first necessary. A letter was sent to all chairpersons (by title) of psychology departments listed in the 1972 *Directory of the American Association of Community and Junior Colleges*. The chairpersons were asked to supply the names of the teachers in their departments and to indicate their status—full time or part time. A follow-up inquiry was sent to the president of the nonresponding institutions. In all, the names of 3,812 teachers (representing about 70% of the institutions) were submitted. A four-page questionnaire² was then sent to each teacher in an attempt to find out something about his training and present needs. At the time the information was compiled, 798 individuals (21%) had returned the questionnaire.

Table 1 shows the location of the teachers' employment. At least one person responded from each of the 50 states and the District of Columbia. Responses were also received from three Canadian provinces and a number of United States territories. California led with 143 responses; New York was second with 52 responses.

Teachers were asked in what type of two-year college they were employed. Table 2 shows a summary of responses to this question. The total number responding was 1,075 because a number of respondents classified their school in more than one category. It can be seen from Table 2 that most two-year college teachers of psychology were employed in public and comprehensive community colleges. Further, most of the teachers (89%) were full-time employees. Among those who worked part time, 34 (42%) were professional psychologists, 20 (24%) were staff members of other colleges or universities, 5 (6%) were high school teachers, and 7 (8%) were counselors in educational institutions.

The questionnaire listed five professional activities and asked what percentage of time was spent in each. Teaching was found to occupy, on the average, 61.7% of the respondents' time, counseling approximately 25%, administrative responsibilities 12%, research 9.8%, and community relations 6.6%.

TABLE 1

Responses by Location to the Questionnaire

Number responding	Location
51 and over	California, New York
41-50	Illinois, Michigan, Texas
31-40	Florida, Pennsylvania
21-30	Maryland, Massachusetts, Ohio, Washington
1-10	27 states, District of Columbia, 3 Canadian provinces, U.S. territories

363	34	Comprehensive community college
72	7	Private two-year college
47	4	Technical school
36	3	Branch of university
21	2	Two-year college with university affiliation
14	1	Other
Total 1,075	100	

The final background information on the sample deals with educational training. Table 3 summarizes the highest degrees held by respondents. The majority of respondents appeared to have master's degrees in psychology; only 139 (18%) of the sample had PhDs and 51 (7%) had EdDs; 221 (29%) teachers were working toward an advanced degree, either a PhD or an EdD, but 529 (71%) were not actively pursuing higher degree levels.

Asked if their graduate education had included special training for teaching in the two-year college, 573 teachers said no (75%); the remaining 192 (25%) who responded to this question said that they had courses on junior college teaching and community college curriculum and had participated in either an internship or teaching assistant program. Most of those who had special training (86%) found it valuable. The most valuable components of special training, among nine listed choices, were considered to be units on individualizing instruction, instructional methods, evaluation of student achievement, and curriculum development; only about 35% felt that their graduate teaching internships had been helpful. Specific courses such as history, philosophy, objectives of the two-year college, and faculty-administration relations were listed by approximately 235 (approximately 30%) of the respondents. About 20% of the teachers found useful a course in problems of higher education. Other helpful aspects of training were listed at a lower frequency, possibly due to their unavailability in most training programs.

Open-ended responses to the question on helpful aspects of training can be grouped into six different areas. The first area is methods of teaching. Here, innovative techniques, audiovisual aids, communication skills, and group dynamics were considered

helpful for presenting materials in the actual classroom setting. The second area most often mentioned can be characterized as skill in understanding the junior college student, including motivation, life-style, needs, age group, and minority status. Third, teachers found courses in counseling and advising techniques to be of help. Since almost one quarter of the teachers' time is spent in counseling, this should certainly have a place in training the two-year college teacher. A fourth area of importance was preparing lessons in applied psychology for students taking only one or two psychology courses or planning to enter vocational rather than academic fields. Human relations training and humanistic approaches were grouped together in a fifth area, and self-evaluation skills was the sixth area.

The most important aspect of the survey is summarized in Table 4. If APA plans to improve and expand its services for two-year college teachers, these data can be used as a basic needs assessment summary. A list of 10 possible association activities was presented to the survey population, and they were asked to rate each from very important to very unimportant. An open-ended question allowed them to list activities that were not in the 10 possibilities. The total number of teachers responding is given in the final column of Table 4. Activities are listed in descending order of importance to respondents. The responses show an overwhelming interest in improving communication, expressed as 80% agreement among respondents that developing a resource center, sponsoring meetings, and developing a periodical should be considered among the most important activities of the APA.

The actual wording of the activity receiving highest priority was "development of a resource center (clearinghouse) for instructional materials,

TABLE 3

9. Increase professional committee involvement	190	285	224	58	18	775
10. Compile a national register	111	229	277	137	70	791

Note. Rating scale: 1, very important; 2, important; 3, slightly important; 4, unimportant; 5, very unimportant.

educational consulting services, etc. . . ." Undertaking such a project would probably mean obtaining a grant from some outside source. Since clearinghouse organization and operation are often grant supported, a clearinghouse for two-year college teachers of psychology could be adapted from models already existing in related disciplines. There is much to be said for initiating this activity at the present time. For example, it is expected that before the end of the decade an educational satellite will be launched to provide communication between classrooms and resource centers throughout the country. It would be most useful to have at least a nucleus center established by then.

Two-year college teachers also felt that APA should sponsor more regional and local meetings for two-year college teachers of psychology, including workshops, programs at meetings of psychological associations, etc. Until recently, most programs at the regional association meetings and the national APA Convention have had little to offer two-year college teachers. Programs generally have been research oriented rather than teaching oriented and have been run by PhDs for small groups involved in similar research projects. Travel to the meetings is expensive, as is registration. It is increasingly more difficult to gain administrative approval and reimbursement for travel to professional meetings, even for many four-year college instructors, and without a meaningful program it is almost impossible for the two-year college instructor to get this administrative support. If programs could be provided closer to home and with greater participation by the teachers themselves, this problem might be overcome.

Items 5 and 9 in Table 4 are related to the problem of professional meetings. The responses to these items indicate that many teachers are interested in being more involved in work at the regional, state, and local levels. Table 5 summarizes teachers' interests in professional association activities. Although 28% of the respondents were members of the APA, only about 5% have been active. In response to the question, "Which psychological associations would you like to be most involved in?" highest interest was shown in local associations, with state, regional, and national associations following in that order. Only 34 (4%) of the population sampled had participated in special sessions for two-year college teachers held in conjunction with 1972 regional psychological association conventions. Asked if they would like to participate in similar meetings in the future, an overwhelming 608 (90%) responded affirmatively. It appears that there is high interest among two-year college teachers in attending appropriate meetings and workshops.

The third area that could be subsumed under improved communication is that of developing a periodical. For the last few years various groups within the APA have urged the development of a journal specifically designed for the teaching of psychology. Most other disciplines already have this kind of publication. If a journal were chosen as the best vehicle for exchange of information, a special section might be devoted to issues concerning the two-year college instructor. It must be remembered that the community and junior colleges generally serve a much more diverse group of students than do the four-year institutions. Students' abilities and goals are often quite different from those seeking the BA or BS degree. At the same time, it should be noted that one third to one fourth of all college graduates start in junior colleges. Therefore, it is essential to provide them with

TABLE 5

Interest in Professional Association Activities

courses that will be credited and meaningful in their later training.

Of the respondents, 72% assigned a rank of 1 or 2 to Item 4 in Table 4, articulating training levels. Improved articulation of programs across training levels could avoid much repetition and waste of course requirements. It could also lead to the development of a career ladder within the field. Items 6 and 8 in Table 4 reflect on the training of the teachers themselves. In the earlier discussion, important and helpful aspects of training were revealed, but it was noted that the majority of institutions provided no training experiences specifically designed to prepare the teacher of psychology.

Moderate interest was shown in the development of data on employment practices in the job market (Item 7, Table 4). It is likely that persons seeking employment at the two-year college level apply directly to the school in the area where they wish to teach; therefore, efforts to maintain an updated employment file would be less important than efforts to generally upgrade professional standards and support in other areas. Similarly, maintaining an up-to-date national register of two-year college psychology instructors was not considered of utmost importance (relatively speaking) by the teachers themselves (Item 10, Table 4); however, it would be most valuable to anyone attempting to organize meetings or disseminate information on a national level. This activity may be more of a necessary record-keeping service than an actual service to the two-year college teacher.

In response to the open-ended question asking for activities the teachers would like to see the APA undertake, a number of workshop possibilities were generated. Interest appeared to be high in instructional techniques, resources (including audio-visual material and texts), new developments in research, workshops between two- and four-year college instructors, interdisciplinary opportunities for curriculum development, psychology in industry, psychology in law enforcement, and psychology in medicine and psychotherapy. Teachers asked for support in academic freedom, flexibility of class arrangements, increased opportunities for graduate study and research, and help in course development. They would welcome financial support for travel and research as well as more reasonable professional fees. A request was made for the development of a master-teacher system whereby a partnership is arranged with a scholar in a senior institution. Teachers would like to be able to exchange their assignments with instructors in other parts of the country, and they would like to see summer institutes for training sponsored by the national association.

If the American Psychological Association decides to assist the two-year college professional teacher, the needs and priorities are clearly established. All that remains is to determine how much of APA's resources will be allocated to this group or whether alternative mechanisms should be developed to help them help themselves.

Eighty-Second Annual Convention of the American Psychological Association

Convention Information

THEODORE G. DRISCOLL, JR. *Convention Manager*

CARL N. ZIMET *Chair, Board of Convention Affairs*

And that is where the 1974 Convention of the American Psychological Association will be held. The dates of the Convention are **August 30 through September 3**. While August is not the ideal time to be in New Orleans, the attractions of the city should compensate for the heat and humidity. Meetings are scheduled in the **Fairmont Hotel, the International Hotel, the Marriott Hotel, the Monteleone Hotel, the Royal Orleans Hotel, and the Rivergate Exhibition Center**. The bulk of the Convention program is scheduled between 9:00 a.m. and 6:00 p.m. during the five days of the meeting. Because hotels are fairly close to one another, APA is not planning to run a shuttle bus among the hotels. Public transportation buses run up and down Canal Street every few minutes at a cost of 15 cents per person.

Canal Street, New Orleans' main thoroughfare, separates the French Quarter from the business district and uptown area of the city. There are historical

sights, shops, nightclubs, and restaurants within the French Quarter. In order to sample the cuisine in local restaurants it would be wise to make reservations for all meals. A handy reference on inexpensive and good restaurants is *The New Orleans Underground Gourmet* by Richard H. Collin.

Transportation from the New Orleans International Airport to the downtown area is available by taxicab or limousine. It takes about 30 minutes to make the trip. The taxicab fare is approximately \$9 plus tip for one to three persons; there is an additional charge of \$3 per person for more than three. Limousine service is available directly to the hotels at \$3 per person. Public transportation is also available from the airport for a fare of 35 cents, but it may be necessary to transfer to another bus within the city in order to get directly to your hotel. See you in New Orleans!

Housing

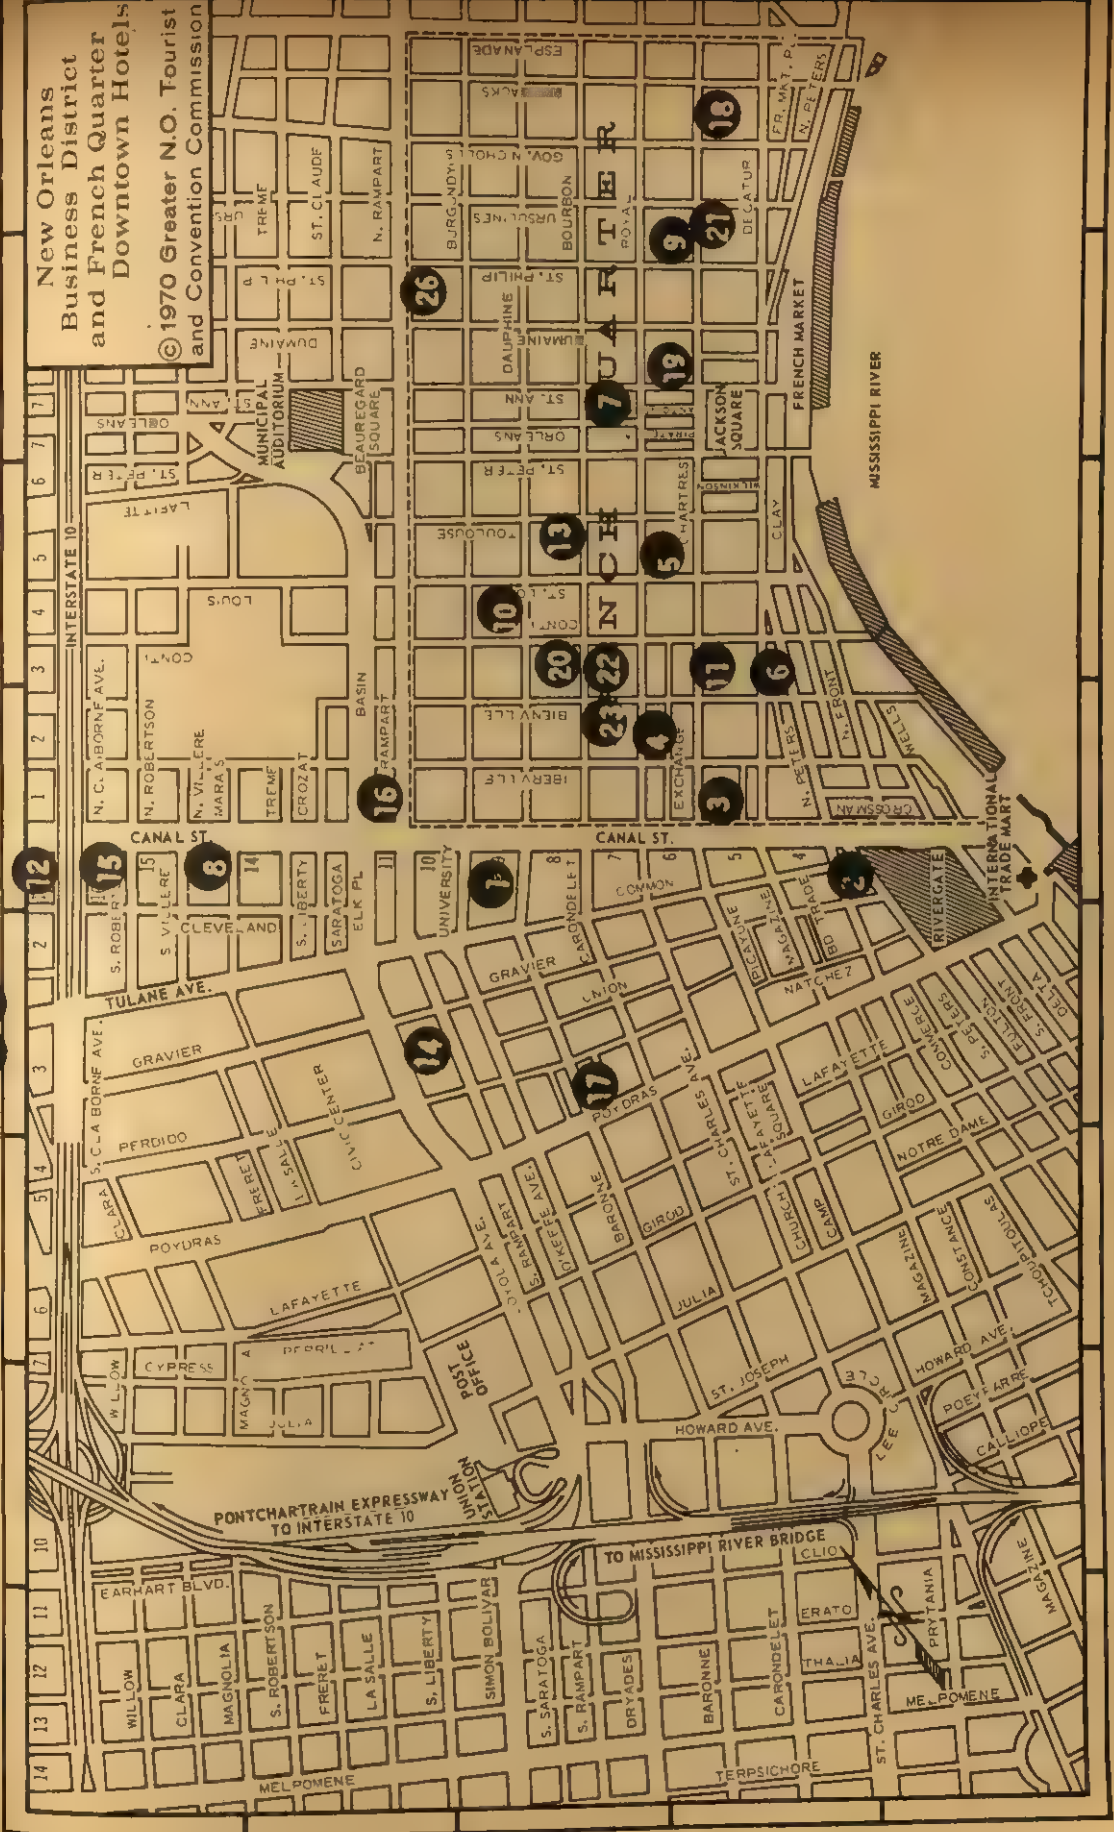

In cooperation with APA, all of the hotels have set aside, at guaranteed rates, substantial blocks of rooms. These hotels have guaranteed rates for the Convention only when registration is made through the APA Housing Bureau on the official Hotel Reservation Form. Also, these rates are guaranteed only when the Advance Registration Form and Hotel Reservation Form are returned *prior to August 1, 1974*. After August 1, every effort will be made to assign rooms at the guaranteed rate, but such assignments cannot be certain, and it is quite unlikely that late requests can be honored.

Members should also bear in mind that with the large number of rooms used, some members may not be assigned a room in the specific hotel they requested nor the type of room at the rate requested. It is advisable to return the Advance Registration Form and the Hotel Reservation Form as early as possible. These forms appear at the end of this issue.

All housing forms are sent from the Central Office to the New Orleans Convention Bureau for room assignments. We anticipate a three- to four-week lag between receipt of request in the APA office and your receiving confirmation from the hotel. If after four weeks you have not heard from New Orleans, please contact di-

and Convention Commission

rectly the New Orleans Convention Bureau, 334 Royal Street, New Orleans, Louisiana 70130.

Wheelchair Accessibility

To facilitate making hotel reservations for those people concerned with wheelchair accessibility, Division 22, the Division of Rehabilitation Psychology, compiled the following information on the accessibility of some of the Convention hotels. Wherever possible, the information has been corroborated by site visits made by knowledgeable persons. Detailed information about the accessibility of various churches, restaurants, museums, and stores may be obtained by writing for a free copy of *Guide to New Orleans for the Handicapped* from Louisiana Chapter, National Society for Crippled Children and Adults, Inc., 843 Carondelet Street, New Orleans, Louisiana 70130.

Rivergate Exhibition Center

Main entrance: Accessible
Restrooms: Accessible
No sleeping rooms

International Hotel

Main entrance and elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Two meet accessibility requirements and must be requested.

Monteleone Hotel

Garage entrance and three elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Hotel has 56 accessible sleeping rooms which must be specifically requested. They are rooms on the fifth floor in the following series: 53, 56, 57, 58, 63, and 69.

Fairmont Hotel

One of the main entrances to the hotel is ramped.
Public restrooms: Women's—accessible
Men's—inaccessible
Sleeping rooms: Inaccessible

Royal Orleans Hotel

Main entrance: Assistance available to negotiate the steep ramped entrance from garage and staired main entrance.
Elevators: Accessible
Public restrooms: Accessible
Sleeping rooms: Inaccessible

Marriott Hotel

Main entrance: Accessible
Elevators: Accessible
Public restrooms: Inaccessible
Sleeping rooms: Inaccessible

Royal Sonesta Hotel

Main entrance: Accessible
Elevators: Accessible
Public restrooms: Inaccessible
Sleeping rooms: Inaccessible

Persons requesting wheelchair-accessible accommodations should check the appropriate box on the Hotel Reservation Form as well as indicate the hotel and type of accommodation requested.

Registration

Convention attendees are urged to register for the meeting in advance. Not only will advance registration assist APA in planning for the meeting, but advance registration represents a saving to the registrants as well as the opportunity to obtain desired hotel space and rates. At its meeting on January 18–20, 1974, the APA Council of Representatives approved the following registration fees for the 1974 Convention:

For those registering in advance (prior to August 1, 1974):

\$30—Nonmember
\$20—APA Member, Fellow, Associate, Foreign Affiliate,
High School Teacher Affiliate

For those registering on-site in New Orleans:

\$35—Nonmember
\$25—APA Member, Fellow, Associate, Foreign Affiliate,
High School Teacher Affiliate

21. Provincial Motor Hotel
22. Royal Sonesta Hotel
23. Saint Louis Hotel
24. Tamanaca (Best Western) Downtown Motel
25. Thunderbird (Quality Inn)
26. Vieux Carre Motor Lodge

Students and other authorized exemptions from these fees appear on the Advance Registration Form.

The convention badge, with name and institutional affiliation, will be mailed in advance of the Convention to those who preregister. Advance registrants will need only to obtain a badge holder at the APA registration area in New Orleans to complete the procedure—thus avoiding possible delays.

Complete member and nonmember registration facilities will be maintained at three locations—the Fairmont Hotel, the Marriott Hotel, and the Rivergate Exhibition Center—according to the following schedule:

Thursday, August 29, 3:00 p.m. to 9:00 p.m.
Friday, August 30, 8:30 a.m. to 5:30 p.m.
Saturday, August 31, 8:30 a.m. to 5:30 p.m.

From Sunday, September 1 through Tuesday, September 3, registration facilities will be available only at the Rivergate Exhibition Center. Hours will be 8:30 a.m. to 5:30 p.m. on Sunday and Monday; 8:30 a.m. to 12 noon on Tuesday.

Placement

The APA Convention Placement Office will be located in the Rivergate-South Hall. Hours will be from 9:00 a.m. to 5:00 p.m., August 30–September 3, except 1:00 p.m. closing day. Fees required are as follows:

Applicants—\$2 for reproducing (1) availability information. \$3 for use of Convention Placement facilities includes a copy of the *Position Openings Bulletin*. (Nonmembers will be charged \$20 for use of Convention Placement facilities.) July 19, 1974, is the deadline for applicant listing. Appropriate fee must accompany listing.

Employers—\$5 for reproducing (1) Job Description. \$10 for use of Convention Placement facilities includes a copy of the *Availability Notices Placement Bulletin*. July 26, 1974, is the deadline for employer listing. Appropriate fee must accompany listing.

Employers: Please note the addition of the GENERAL OPENINGS category to be used by organizations hav-

ing widespread needs for psychologists who may be recruited through a central office.

Prelisting in the more widely distributed printed booklet is encouraged, but Xerox forms will be available for on-site listing. The forms, accompanied by the appropriate listing fee, must be received by the date indicated above. Please do not include the Convention Placement facilities fee which will be collected ONLY when you register at the Placement Office. After the above date, Xerox forms will be available for listing, and requests should be directed to the address below.

A complete set of applicant availabilities will be available to employers: \$15 for each category—please indicate choice. After the Convention, order from the Convention Placement Office, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Mail orders for the printed *Availability Notices Placement Bulletin* and the *Position Openings Bulletin* are \$1.50 per copy (available August 7). Your check (no billing) may be sent to the above address.

Convention Personnel

You may wish to contact one or more of these people before or during the Convention:

Board of Convention Affairs: Carl N. Zimet, Division of Psychology, University of Colorado School of Medicine, Denver, Colorado 80220.

Convention Manager: Theodore G. Driscoll, Jr., Driscoll and Associates, 7109 Masters Drive, Potomac, Maryland 20854.

Assistant for Convention Management: Candy Won, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Placement Office: Robert L. Campbell, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Please Note

Meetings for Divisions 19 and 21 will be located in the *Monteleone Hotel* rather than the Royal Orleans Hotel as noted in the April convention insert.

Convention Child Care Service

Provision has been made for a professional child care service during the 1974 Convention. CON-SERV has been engaged and will offer an extensive program.

Parents desiring to use child care facilities must preregister no later than July 15, 1974. To preregister, complete the form at the bottom of this page. Please note that upon filing of the preregistration form and payment of the advance deposit as indicated on the form, CON-SERV will provide complete detailed information about the services offered and final registration materials necessary to plan for your children's comfort and safety. If for any reason your plans change, the deposit will be refunded in full if CON-SERV is notified of cancellation by August 10.

Some of the essential features of this service, as planned, are indicated below:

- The facility will be located in Braniff Place Hotel and will be open from 8:00 a.m. to 6:30 p.m., August 30–September 3, 1974. While the cost will be about \$1.50 per hour per child, APA will subsidize \$.75 of this cost. Hence, the cost to parents during the daytime will be \$.75 per hour per child.
- If there is sufficient need, the facility will remain open after 6:30 p.m. until 12 midnight to accommodate

parents who may wish to leave their children in the facility during evening hours. The parents will bear the full cost during these hours. If the need for evening child care does not justify keeping the facility open after 6:30 p.m., personnel at the facility will make every effort to help individual parents locate qualified babysitters to stay with children in their hotel rooms for those who might need this service. In any event, every effort will be made by CON-SERV to assist parents with evening child care arrangements.

- During the regular daytime hours, a variety of optional tours will also be offered at modest cost to parents. APA will subsidize part of the cost to the extent of \$.75 per hour per child as though the child were in the facility.

- In order to evaluate the child care services at past conventions, the Task Force on Convention Child Care would like you to answer the following questions: (a) What was your general reaction to past child care facilities? (b) What was the least-liked aspect? (c) What was the most-liked aspect? (d) What was needed and not provided? Please attach your answers to the preregistration form.

Preregistration Form: Child Care Service—APA Convention New Orleans, Louisiana, August 30–September 3, 1974

Preregistration form must be returned no later than July 15, 1974.

Name of Parent or Guardian: _____

Street Address: _____

City, State, Zip: _____

Name(s) of children to be registered in the child care facility:

Name	Age
_____	_____
_____	_____
_____	_____

If your child has a specific problem or handicap that we should be aware of, that is, speech impediment, retardation, epilepsy, etc., please let us know so that we may make the necessary provisions. _____

Please check this box if you are interested in tour information for your child

Signature of Parent or Guardian

Please return this form to Ms. Diane Snow, Con-serv, 1318 Arabella Street, New Orleans, Louisiana 70115, and enclose a check in the amount of \$7.50 for one child or \$15.00 for two or more children as listed above. Make checks payable to "Con-serv." Indicate amount enclosed: \$_____.

NOTE: This is only your preregistration form. Upon receipt of this form you will be furnished complete registration materials.

Employers of Psychologists:

If you have or anticipate openings for psychologists, you may wish to list them with the APA Convention Placement Service. The Job Description Form below is for this purpose. Additional copies supplied upon request.

A service fee of \$5.00 per insertion will be required for listing in the **Convention Placement Bulletin**. FEE MUST ACCOMPANY COPY—no billing by APA—DEADLINE JULY 26. If you recruit at the Convention, an additional \$10.00 fee will be required for use of the Placement Office facilities. This fee payable ONLY when you register at the Placement Office.

The FINAL FORM of your job description below will be the actual copy used in photo offset printing of the **Convention Placement Bulletin**. The box thereon is the maximum space usable. An illustration and a work form are provided for your guidance. Only clean typed copy within the boundary on the FINAL FORM will be accepted for publication. Please list your job data of the kind and in the order illustrated. Do not skip any lines. Thank you.

Standards for Educational and Psychological Tests

1974 revision.

Developed under a grant from the Russell Sage Foundation by a joint committee of members from the APA, the American Educational Research Association, and the National Council on Measurement in Education.

This current revision of **Standards** is directed equally toward establishing guidelines for test developers and test users. It proposes *essential*, *very desirable* and *desirable* considerations for the effective development and use of standardized tests. Additionally, each standard is accompanied by an exemplary or clarifying comment. 80 pp. \$3 to APA, AERA, and NCME members; \$5 to nonmembers.

Contents:

Introduction

Standards for Tests, Manuals and Reports

Standards for Reports of Research on Reliability and Validity

Standards for the Use of Tests

Please note that payment must accompany all orders amounting to \$15 or less except for those orders submitted on institutional purchase order forms.

Comment

Graduate Training in Philosophical Psychology

I was instructed by the Executive Committee of Division 24 to bring to the attention of the larger psychological community the results of a survey on graduate training in philosophical psychology sponsored by the Division. The results of the survey follow. I think the findings speak for themselves and I shall let each of you draw your own conclusions.

1. Total number of schools written to = 305.

2. Total number of schools responding = 160.

3. Sources of information:

Anonymous written note	30
Note by chairman	67
Bulletin (brochure, flyer)	37
Personal letter	26
Total	160

4. Is there a specialty offered in philosophical psychology?

Yes = 5 No = 155

5. If Yes, then what is the nature and extent of it?

(a) Georgia State University, Atlanta: Foundations of Psychology Program still in formative stages.

(b) Union Graduate School, Antioch College: Union Graduate School designs the program for each student to fit his background, needs, and goals. A few do major in philosophical psychology, all are PhD candidates.

(c) University of Ottawa, Canada: Specialty in philosophical psychology is open to any PhD candidate who should elect it. There are psychology professors competent in this area to guide the candidate in his academic work.

(d) Duquesne University: Existential phenomenological philosophical approach is applied to numerous psychological problems at both the MA and PhD levels.

(e) Center for Advanced Study in Theoretical Psychology, University of Alberta, Canada: The Center is a doctoral and postdoctoral research organization devoted to the clarification of conceptual problems in psychology and investigation of the field's theoretical-philosophical presuppositions.

6. If No, then is there an emphasis on theoretical psychology?

On "Obedience to Authority"

Obedience is not to be understood solely by reference to the individual's conforming deed; that is merely the end product of a long process of prior programming by which the rationality of power, dominance, and authority become impressed upon us. We are controlled not by the physical strength of adversaries but by the symbols, rules, and words manipulated by those of our own kind. The technology of behavior control begins with the subtle family processes involved in "civilizing" infants to be "good," "acceptable" children. The major lesson taught in all traditional school systems is the necessity to obey trivial, irrelevant rules and to observe protocol, while at all times respecting authority because it exists. Such control is perfected by a variety of social institutions that encourage adults to exchange freedom of thought, independence, and individuality for the delusions of social and economic security, collective political strength, and personal approval.

I believe that the three major themes of Milgram's research (for review, see Milgram, 1974) and of our companion research on simulated

prisons (*New York Times Magazine*, April 8, 1973) are

(a) that obedience to authority requires each of us to first participate in the myth-making process of creating authority figures who then must legitimize their authority through the evidence of our submission and obedience to them;

(b) that the reason we can be manipulated so readily is precisely because we maintain an illusion of personal invulnerability and personal control, all the time being insensitive to the power of social forces and "discriminable" stimuli within the situation, which are in fact the potent determinants of action; and

(c) that evil deeds are rarely the product of evil people acting from evil motives, but are the product of good bureaucrats simply doing their job.

Rather than misfocusing attention on the ethics of Milgram's research, the dramatic aspects of the subjects' conflicts, or the ingeniousness of the experimental contrivances, we should focus on the very different concerns that are engendered by a meaningful reflection on *obedience to authority*. We must first increase our sensitivity to, and our need for, more knowledge about those conditions in our everyday life where, despite our protest—"I would never do what they did"—we would, and we do, behave contrary to our expectations. Second, we must critically reexamine the ethics and tactics of our revered social institutions, which lay the foundation for our mindless obedience to rules, to expectations, and to people playing at being authorities.

The question to ask of Milgram's research is not why did the majority of normal, average subjects behave in evil (felonious) ways, but what did the disobeying minority do after they refused to continue to shock the poor soul, who was so obviously in

pain? Did they intervene, go to his aid, denounce the researcher, protest to higher authorities, etc.? No, even their disobedience was within the framework of "acceptability"; they stayed in their seats, "in their assigned place," politely, psychologically demurred, and they waited to be dismissed by the authority. Using other measures of obedience in addition to "going all the way" on the shock generator, obedience to authority in Milgram's research was total!

Such an experimental result is more than merely "probably important" (as Steven Marcus's review in the *New York Times*, January 13, 1974, suggests). It ought to give each of us pause as no other single bit of research has. But it will not, because the vital lessons about human conduct are really not influenced by research psychologists or heeded even when nicely expressed by English professors. The lessons reach the people through their momma and poppa, the homeroom teacher, the police, the priests, the politicians, the Ann Landers and Joyce Brothers, and all of the other "real" people of the world who set the rules and the consequences for breaking them.

Reinterpreting Sarason's Blackishness

Psychological science could benefit significantly from further examinations of nature and nurture issues as presented by Sarason (November 1973). The long-range payoff in

societal amelioration and true human development would be evident. On the other hand, behavioral scientists who promote quasi-scrutinous evaluations of the confounding matrix of "nurture" variables also could be handicapped by Sarason's insistence on using a comparative model: blackishness versus Jewishness. As a black psychologist who has devoted much thought to racial-ethnic psychodynamics, I find such ethnic parallelism highly inappropriate and objectionable. It becomes increasingly obvious to me that until the real dimensions of nurture as explicated from differential intraethnic perspectives are fully explored, the real danger exists not in the metatheories of advocates promoting genetic inferiority (of blacks) but in the environment-nurture camp whose perspective is weak, faulty, and misguided.

First, to counter Sarason's notions let me present a series of arguments that should expose the fallacy of a comparative analysis between the black and the Jewish experiences:

1. While a fairly large number of Jews seem to have inculcated "a respect for book learning," it would be fallacious and deceptive to assign this proclivity to the overwhelming majority of Jewish persons. The broad-based Jewish scholarship in many fields is frequently used as the empirical yardstick of Jewish achievement, yet quantitatively this phenomenon represents neither innate superiority nor a unique "nurturance for scholarship" factor. A constellation of various political, economic, and religious considerations has contributed significantly to Jewish advancement. At present, no other minority group has had the opportunity to even approach this level of accomplishment in America.

2. Sarason stated that "blackishness has not had at its core unbounded respect for book learning and the acquisition of academically soaked, cognitive skills [p. 968]." Such a notion typifies a weak diagnosis of social phenomena. Actually, the real issue here is that historically,

American institutions have deliberately and consistently engaged in denying and excluding black people from educational achievement. The fact that large numbers of blacks have still managed to endure and achieve represents human accomplishment that has few parallels.

3. The attitudinal core of blackishness, for example, toward education, does not require a modicum of change as Sarason suggested. The real change is needed fundamentally in America's social, political, and educational institutions and in those individuals who have promoted oppression.

4. Although Sarason is correct in asserting that societal amelioration must occur within a context of a time perspective, his allegiance to time has potentially dangerous political implications. Our policymakers could very well interpret such a perspective as indicative of the need to minimize, or even discontinue, such programs as Head Start with such rationales as "It's too early to know if the program has really worked" or "the small IQ gains don't justify the cost benefit factors."

5. Sarason seriously failed to comprehend the black experience when he asserted that both Jews and blacks believe that "this is a hostile world." In my opinion, many blacks today have not reached this important level of consciousness, but the number is increasing steadily. In fact, I have often advocated that young black children should encounter direct socialization experiences through which they can understand white society, and not their own, as the cause of interethnic difficulties. To many, such enculturation smacks of promoting racial hatred and bigotry as inevitable consequences, but, from my perspective, such developmental experiences would contribute significantly to the future of black mental health.

Sarason's autobiographical account was seemingly written for the purpose of capturing a typical Jewish developmental experience. In a similar vein, my own black autobiography should be equally enlightening, al-

though I disclaim its generalizability to any other black experience. The reason for this disclaimer will be presented subsequently.

Following Sarason's format, let me begin with my father, also a simple and unassuming man. Consistent with many sociological analyses, he migrated during the 1920s from the rural South to a northern metropolitan area, in his case, Washington, D.C. Although undereducated, he did believe, like many blacks, that the educational process unlocked the chains of economic oppression. Unfortunately, he was only able to obtain a night school certificate indicating completion of the eighth grade because the Washington school system made no provisions for adult secondary education at that time. He did not read books, but he was a copious and avid reader of the *Washington Post*. In fact, as a long-range consequence, I am one of those several people who knew BW (Before Watergate) that the *New York Times* is not the world's best newspaper.

My elementary school experiences were significant in molding my orientation toward education and the learning process. Refusing to enroll me in the school directly across from our house, my mother insisted that I travel to a more distant school. She reasoned that her choice was based on the fact that the more distant school's principal was her former fourth-grade teacher who fostered quality education. As a child psychologist I now suspect that she wanted to enjoy the peace and quiet that most mothers cherish when their offspring enter school.

Although my elementary school had excellent teachers, perhaps the ostensibly minor variable of its location contributed to my climbing the academic ladder. This school was only two blocks from Howard University, the center of black higher education. Some of my fondest memories during my elementary school years were roaming Howard's campus engaging in all sorts of children's games, or wandering through

its biology laboratories. During those years, my school friends' choice of adulthood occupations varied as a function of our visits through the campus buildings. At one time it was architecture, later botany, then physics. During these childhood days, I knew I was going to college, but was unaware that I would return to Howard as an undergraduate psychology major.

Like Sarason, I also had a cousin who provided significant role modeling for me. My cousin Bobby, now a prosperous gynecologist, was a Howard University medical student during my elementary school years. He also stopped at our house after classes to conduct his scheduled inventory of our refrigerator and pantry. But most impressive to my young mind was that Bobby always carried tons of books and enjoyed studying them. Even more so, he always received academic honors for his endeavors. Instead of jealousy, my response was basic admiration reinforced by my family's expectation that I would follow in his footsteps. Perhaps the only mistake I made in emulating my cousin's achievements was not pursuing a career in gynecology. In comparison to psychology, it's much more profitable.

My undergraduate experiences at Howard University set the foundation for my subsequent adult experiences as a psychologist. The educational curriculum, typical of many black colleges, was the traditional no-nonsense approach, except for one major difference which many, if not most, black college students are presently denied. My awareness of Howard's unique offering was brought home to me recently when one of my black students commented that I was the first black psychologist she had ever met. My immediate reaction was to discount the student's statement until I remembered that unlike herself, a college senior, my first undergraduate psychology course was taught by a brilliant black psychology professor who also was a significant role model for me.

The remainder of my academic professional career is fairly standard—graduate school, dissertation, research, and teaching, etc. However, although academic-intellectual pursuits have been fairly easy for me, I have always recognized that my achievements have been keynoted by chance. For example, most of my childhood and adolescent peers did not go on to college and graduate school. Many of my childhood acquaintances are members of what social science has labeled the "culturally disadvantaged." It is my belief that such "options" were also available to me, and I count myself among the too few fortunate blacks who have excelled in the academic arena.

My exceptional developmental experiences have direct implications both for the future of black children and for Sarason's notions of nurture. First, unlike Sarason's claim of a commonality in the Jewish experience, black achievement (and failure) is ineligible for comparisons to other ethnic groups because of its great diversity and heterogeneity which many blacks are beginning to consider as strengths. Second, instead of considering time as a variable in societal amelioration, social scientists need to examine the intensity and pervasiveness of society's commitment to social advancement. Many blacks have long recognized that this nation's dedication to eradicating oppression, racism, and poverty is equivocal, at best. Finally, Sarason needs to understand the true and positive implication of the black adage: Any black man who is not paranoid must be crazy!

You Have Got to Have a Dream, But It's Not Enough

Having grown up in Jewish families, being psychologists, and having followed Seymour Sarason and his contributions to psychology and human welfare (he completed graduate school the year we were born), we would like to comment on his thesis and then try to pick up where he left off in his recent article (Sarason, November 1973).

On the face of it, Sarason's thesis on the difficulty of using short-term psychological or educational interventions to alter historically rooted and culturally transmitted ways of viewing the world may be accurate. However, we are left with an uneasy feeling about what that thesis implies for the future of psychoeducational or other social change interventions. We fear that Sarason's arguments, left without further comment, may inadvertently be construed to support "benign neglect" and other such forms of status quo social policy. This is particularly critical today when there appears to be a halt to, or movement away from, social change and reform. For example, on our campus last week there was a minuscule demonstration by black students protesting the fact that changes for black people are no longer "in style."

To argue that the power of cultural transmission is so overwhelming that one needs to think in terms of a century in order to see significant alterations in the status of minority groups is most important if the goal is *assimilation*, but less important if *accommodation* is the aim. Viewing the issue in this old-fashioned sociological terminology makes it clear that the problems discussed by Sarason may not simply necessitate strategies for changing minority groups but rather *require* strategies for changing the *majority*. The question is not simply how to change the internalized social attitudes of the minority culture via the socialization process but how to change the objective opportunity structure for mi-

norities, as well as the attitudes and behaviors of the majority.

Although Sarason briefly noted the problem of "blaming the victim," he did not point out, as did William Ryan (1971), that blaming the victim involves the attribution of responsibility for some socially defined problem to the minority individual. The problem may be viewed as a result of genes, home life, ability, background, etc. While Sarason excluded genes, "cultural transmission" encompasses all of the other blaming strategies.

Given that the cultural attitudes transmitted by Jewish and black families have been dissimilar in regard to education, it is understandable that these two cultures will produce different numbers of "successes," as defined by an educational criterion. As Sarason is aware, that is not the only criterion by which groups can be compared. For example, a stereotype comparable to the Jewish intellectual might be the black jazz musician. There is little objective basis for choosing who is more worthwhile—a college professor or a jazz musician. That is a matter of values. An article like Sarason's could be written by a black jazz musician arguing that the problem for Jews is not that they do not have good rhythm or "soul" genes, but that Jewish culture does not emphasize music in the way that his family and friends' and cousins' families do. That would not help to produce more Jewish jazz musicians, to encourage such efforts, or even to understand what it is that makes one a good jazz musician.

It is not debatable that values are in question here. One is bordering on trouble when he implies, however understandingly, *why* this is the case, that one man's family transmits better values than another's. Sarason was clear on the relativity of the criterion when he discussed genetic explanations. He was not clear when he discussed the outcome of socialization processes. His arguments allowed the conclusion, albeit inadvertently, that we need a kind of

social eugenics, or a means of getting black families to teach their children the proper values, especially the value of education. Of course, this takes a long time.

We could all agree that it is important that the opportunity structures be open to blacks, whites, Jews, or whomever, on the basis of a desire to pursue a given set of values and goals. The problem, however, for blacks in the educational system is not only that there are not enough blacks in the system but, more specifically, that blacks who *potentially* may want to get into the system are not allowed in. This restricting of opportunity does not have to be enforced by traditional and obvious forms of discrimination. Take, for example, a primary-school black child whose mother wants him to be educated every bit as much as did the Jewish mother who lived in the same house several generations before. When this child is taught in school not to value education because the white teacher, who cannot understand black dialect, concludes that this child's family does not give him the "proper" background, we are not dealing with a problem of minority group cultural transmission. We are dealing with a *majority* group cultural transmission that does not afford the minority the equality of educational opportunity. A recent study by Rubovits and Machr (1973) demonstrated the potentially devastating effects of even positively manipulated teacher expectations on black children.

And what about the positive side? What kind of psychoeducational and social policies do encourage social change? First, programs that support a minority group's strengths, rather than seek out their weaknesses, are imperative. Also desirable are programs that teach standard English as a second language and that start with a child's individual ability to learn transfer skills so as to make use of cultural amplifiers (Cole & Bruner, 1971). Second, working to change the attitudes and behaviors of the dominant cultural majority

seems essential. This does not mean ignoring the problems of the minority but, rather, entering into such problems with the realistic optimism that these are people with as many strengths as any other group.

Gurin and Gurin (1970) had a particularly good analysis of the problem of changing individuals versus changing society's opportunity structure. They applied Rotter's (1954) social learning theory, which argued that the likelihood of a given behavior being performed is a function of the expectations one has that the behavior will lead to some goal, and the reinforcement value of that goal. Gurin and Gurin (1970) argued that for people who are poor, many things have the same reinforcing value as they do for middle-class people; the poor do not want things substantially different. The problem, in this view, becomes the subjective expectations that going to school, getting a job and working for success in that job will lead to the things one values. For many minority people such expectations are low. To deal with the problem of low expectations is to work at changing the subjective probabilities that a given behavior such as going to school will lead to success in life. If a minority person raises his or her expectations in the absence of changes in the external objective opportunity structure where the real probabilities rather than the subjective probabilities lie, he or she may be moving toward disappointment and failure. On the other hand if there are changes in the external opportunity structure that are not perceived at the individual level a minority group member may not take advantage of the changes. From Gurin and Gurin's (1970) analysis it is clear that one cannot ignore the cultural transmission of expectations but one also must simultaneously work to change the external opportunity structure.

Having discussed several suggestions concerning the content and direction of future social change interventions, we turn now to a consideration of the form of these in-

terventions. Hopefully one would not conclude from Sarason's article that a long-term intervention, that is, a century, is the only meaningful form. Obviously, any contemplated intervention of such long duration is not only politically and personally unrealistic but ignores a rapidly changing world.

On the other hand, we need to engage in a series of short-term interventions in a somewhat paradoxical fashion. We need to have, and more importantly to communicate, high expectations for the efficacy of our short-term interventions, while not being discouraged by our modest accomplishments. Achievement rarely, if ever, matches one's goals; however, if our goals are set and communicated at a minimum, we are bound to accomplish less than if they are set at a maximum. Politicians think of massive social change occurring during a single term of office. We must not let this phenomenon lead to pessimism and the curtailment of continued thought and energy on our part. Instead, we must continue to push forward with the next phase and the concomitant revision of specific goals and methods in quest of our long-term aims.

Failure, or more realistically partial failure and partial success, is not only negative. The feedback from this failure leads to progress. The fact that we lost the war on poverty taught us a great deal about how social change requires more than working with the victims, even if we allow them to participate in their own "cure." The civil rights era taught us that laws that supposedly change the opportunity structure are also insufficient for social change. We did not know that until we tried it. Even with failure, there are now more blacks in visible places, for example, on television, in universities, to model for their younger counterparts. Failures can lead to future successes; we should not fear failure.

In pursuing social change we need to set a series of short-term, specific, and realistic goals, as well as long-term aims. We need to work with

the powerful and the majority as well as the powerless and the minority. We can afford the perspective of a century in the solitude of our offices but not in the streets of our cities. We must put together a series of modest advances, all aimed toward a larger future perspective. Our errors in the past have not been due to overoptimism; they have more likely been due to the failure to specify short-term and specific goals in conjunction with our larger dreams.

Jewishness, Blackishness, and the Impending Retreat of Psychology

I would like to commend Professor Sarason (1973) for writing his article on *Jewishness and blackness* in such a personal, meaningful genre. This kind of essay has a vital, illuminating power and has largely been underused in psychology. I have recently returned from spending two years in Tanzania and one month in Israel where I had the opportunity to observe Jews and blacks in other than an American context. Having evolved some ideas from the perspective afforded by a prolonged separation

from the "familiar" I would like to take issue with both the spirit and conclusions of Sarason's article.

What seems to be of critical importance about the Sarason article is the timing of its appearance. On returning to the United States, I was struck by the drastic shift of mood concerning the involvement of psychology in social affairs. The middle and late 1960s saw many psychologists alter their focus of applied and theoretical interest to the "system" rather than the individual (Sarason, Levine, Goldenberg, Cherlin, & Bennett 1966). This spirit was exemplified by the development of programs, journals, and even the tenuous title "Community Psychologist." The 1970s, however, seem to be typified by the rapid erosion of optimism concerning social change and a feeling of disillusionment with the application of the social sciences to solve problems of poverty, racism, and the broad spectrum of cultural evils.

Though Sarason drew no explicit conclusions concerning psychology's future in social affairs, remarks such as "What centuries have produced will not quickly change even under external pressure [p. 967]," certainly have a pessimistic ring. If it is true that psychology is, in fact, withdrawing from its very short-lived assault on the social system, I am very fearful that Sarason's article will provide a rationale for the retreat. It is therefore imperative that some serious flaws in his rationale be identified and discussed.

I should mention that I, like Sarason, am Jewish and can identify with many experiences to which he makes reference. He argued that historically determined characteristics, such as valuing intellectual accomplishment are powerful and difficult to change. He stated, "*These aspects have been and will continue to be immune to change in any short period of time, by which I mean a minimum of a century* [p. 964]."

However, when he attempted to support the position by making reference to Israeli Jews, the argument was weakened rather than strengthened.

Israel provides a perfect example of people in a different situational context, making a rapid and stable transformation. The change from passive victims of fascist terror to a militant people determined to defend their lives and land to "the end" did not take a century, or even generations. Rather, the children of immigrants from Europe and elsewhere have emerged as a *new kind* of person (and Jew), heir to some of the traditions (the intellectual), but with an essentially unique character.

One can also look to a country such as Tanzania to see the same rapid transformation of individuals. Students in both secondary- and university-level training have in one generation moved from a simple peasant social heritage to modern institutions of learning, and have performed admirably. Men and women whose childhoods were spent in huts without electricity, plumbing, or books are now pursuing graduate-level degrees. This phenomenon is occurring in developing countries around the world and I would urge Sarason to take notice.

What Sarason has perhaps identified accurately is the fact that American compensatory programs have not accomplished miracles and that there have not been dramatic changes for blacks in the intellectual arena. His conclusion, however, that change will take "centuries" is both unwarranted and as socially irresponsible as the Jensen (1969) article. If I may borrow from Sarason's analogy of the child who does not learn to read, one need not necessarily conclude that it will take *the child* years to change, thus putting the blame for failure on *the victim*. I do not mean to invoke timeworn platitudes but rather to remind Professor Sarason that programs are often irrelevant, limited in scope, unimaginative, and hence produce no obvious consequences.

Psychology has not even scratched the surface concerning the difficulties of American blacks. Our programs, to date, have been at best piecemeal and have represented isolated and sometimes hasty attempts to correct

the mistakes of history. What has made the difference in places like Tanzania and Israel is the comprehensiveness and consistency of the programs. It would be an understatement to say that we have really not seen any substantial consensual national efforts to deal with the problems of our oppressed minorities.

I take for granted that historical and cultural forces operate to make change a conservative process. However, it is critical to recognize that the process of change can either be facilitated or obstructed by systemic factors. To date, the social and economic environment in the United States has dramatically impeded the aims of any restorative efforts. As one psychologist, I cannot accept the cynical conclusions of Sarason. I genuinely hope that the many psychologists who have lost their direction in the community do not welcome the article as license for abandoning their social responsibilities.

A Reply to Gillen

Gillen (November 1973) reported Flesch formula ratings of reading ease and human interest for 34 introductory texts. This report represents a basic attempt to quantify two factors that might be considered in the selection of a textbook. Our response to the aim of this report is favorable. However, we are skeptical concerning the value of these reported ratings and we remain convinced of the need for more compre-

benign programmatic research to guide decisions about textbooks.

Our skepticism stems from three concerns: (a) no substantial validity has been established for the use of such ratings with introductory psychology texts, (b) the ratings are not based on a comprehensive analysis of physical characteristics, and (c) no mention is made of the variability across sampled passages within the textbooks (Stevens & Stone, 1947).

The only reference to the validity of Flesch ratings for textbooks in Gillen's report was to an article by Stevens and Stone (1947). These authors reported agreement between Flesch ratings and ratings of readability made by students and teachers. Striking differences in both content and structure are revealed by an examination of the textbooks in the Stevens and Stone sample from more than 75 years ago and Gillen's sample today. Flesch ratings do not reflect variability from many of the sources that are more prevalent in the modern introductory textbook. To the extent that raters are influenced by the additional sources, there will be a reduction in the agreement between Flesch ratings and the ratings by judges. McKeachie (1969) has indicated a more important validity concern. If the aim is selection of a textbook, the most important consideration is the utility of the textbook in helping to meet particular course goals.

The second concern from which our skepticism arises relates specifically to the measurement of physical characteristics of modern textbooks. Flesch ratings are based on limited samples of continuous verbal text. Anastasi (1964) stated that one common criticism of the Flesch ratings is that they do not reflect many sources of variability in the verbal text, such as organization, use of inappropriate words or circumlocutions. Additional criticism must be made when Flesch ratings are obtained for introductory texts. A modern introductory text does not typically communicate solely through a continuous presentation of verbal text. Many devices are employed

Graphic tables, photographs, illustrations, chapter outlines, and chapter summaries are commonly used. Many texts also contain relatively unique characteristics such as illustrative autobiographical inserts in the margin and offset boxes with empirical findings. Comprehensive measurement is a feasible method and should be considered an essential foundation. One workable measurement procedure can be developed to parallel Brown and Owen's (1967) approach to forms. Available measures can be applied to the sample of textbooks, and a factoring process can be used to yield physical dimensions. Subsequently, the utility of the resulting dimensions can be determined relative to judges' ratings. Most importantly, relationships can also be determined between factor loadings for texts and success in meeting particular course goals.

The third concern underlying our skepticism centers on the fact that no mention was made of variability across passages within textbooks. This can ultimately be included as one measure in a more comprehensive measurement procedure. Stevens and Stone (1947) lent some attention to the standard deviations in their report. Rosenzweig (1947) suggested that more extensive use be made of the standard deviations reported by Stevens and Stone. For the sample of texts by Gillen, such a measure may have proven even more interesting than it did with the Stevens and Stone sample. The increased interest and information from this measure stem from differences in the two samples. Gillen's sample contained books written by one author and many authors (e.g., Morris versus CRM). In addition, the books in Gillen's sample are typically suited to "basic processes" courses. Variability across topics (e.g., physiological psychology and social psychology) may be considerable and may reflect more than varying a literary style to ease the reading.

A Cautionary Note

Gillen (November 1973) attempted to provide instructors of introductory psychology courses with readability and human interest scores for a number of general psychology texts. Such an endeavor may be of value to some instructors in making text selections, but I feel that Gillen's information did not provide an up-to-date evaluation of several of the books that he surveyed.

Specifically, Gillen overlooked in his analysis the fact that at least six of the books which he evaluated have come out in revised editions. These revisions include Deese (1967), McKeachie and Doyle (1970), Ruch and Zimbardo (1971), Hebb (1972), Munn, Fernald, and Fernald (1972), and Cox (1973). Furthermore, revisions of Kimble and Garms (1968) and Morgan and King (1971) are currently in preparation.

In fairness to the authors of the above texts, their revised editions are probably somewhat more tradable and more human-interest oriented than were the original editions. I make this assumption because (a) feedback from publishers to authors about revisions can be expected to dictate such a course of action; (b) the fact that the books are judged worthy of revision should be some index of how users view the texts.

there seems to be a strong conservative trend within the textbook industry to put out introductory psychology texts which sustain student interest by including more socially relevant material (e.g., Bourne & Ekstrand, 1973; Buss, 1973; Dushkin Publishing Group, 1973; and Gazzaniga, 1973). In this regard, it would be interesting to see how Flech rankings of the original versus the revised edition of various introductory texts compare. If such a comparison reveals significant differences, then Gillen's rankings would have to be updated.

In closing, I would like to emphasize that assessing the readability and interest value of instructional texts is a legitimate problem which instructors must consider. An endeavor should be made, however, to constantly update such rankings as revisions and new books are added to the introductory psychology textbook market.

Psychic Determinism versus Freedom of Choice: Order versus Chaos

This statement is a reply to Tyler's (December 1973) article and a clarification of what determinism implies for psychology and society. Tyler presented some of her thoughts and supporting philosophical writings for the hypothesis that we have freedom of choice even though our actions and thoughts are partly determined. I propose that orderly thought or behavior, which is based on a sequence of choices, is either determined by the external environment or a combination of the latter plus internal causes or control. Behavior which is not determined by some combination of external and internal control that which is completely free is random, chaotic, and possibly detrimental to the behaving individual and the society in which he lives. If Tyler agrees with this definition of behavior, whether or not she agrees that determinism exists, then I would not disagree with her statements. However, if she denies determinism, whether external or internal, and proposes complete freedom of choice, I would definitely disagree with her proposal.

Furthermore, by assuming internal as well as external control of behavior when an individual makes a choice, he can essentially individually determine his course of action. To assume he has complete freedom of choice is an absurdity, because this would imply estrangement from one self, or at least an individual unconcerned of his own motivations and goals. Even if such a mode of existence were possible, I doubt whether such an individual would help society.

I therefore submit that a psychologist who recognizes his own motiva-

tions and goals is freer, in the sense that Tyler emphasized, than one who always is compelled to judge his research or behavior in terms of what "society" considers profitable. Researchers have often rebelled against accepted doctrines of their times, resulting in contributions to the future. Research psychologists are not very different from other researchers in areas such as physics, biology, chemistry, or medicine. If at every step of a research project the investigator had to question his actions in terms of the immediate benefit to society, he would become the proverbial armchair psychologist.

STANLEY MORJANSTEIN
William Paterson College
of New Jersey

Is the "Design for a Hopeful Psychology" Working?

It was heartening to read "Ethical Principles in the Conduct of Research with Human Participants" prepared by Cook and other members of the Ad hoc Committee, APA, Inc. Like earlier APA publications regarding ethical standards, these principles were based on incident reports giving them an empirical as well as an ideological base. A most welcome change was the substitution of participants for subjects.

Then came Tyler's (December 1973) address suggesting among other things that concern for the participants might result in emerging as results. This one might anticipate Tyler's "Design for a Hopeful Psychology" to be already reflected in the recent experimental literature. On the very next page of the *American Psychologist*, however, appeared the article by Mesinger (1973), citing evidence that from 1948 to 1970 the amount of deception in experiments increased in com-

journals, while remaining about the same in others.

During the winter academic quarter ending in March 1974, I conducted a seminar entitled "Ethical Principles in Educational Research and Development." While this seminar was offered as a graduate education course rather than as a psychology course, the students agreed to use as their guidelines the APA publications that formulated ethical principles. After the students demonstrated knowledge of and concern for the ethical principles stated in the document by Cook and others (APA, 1973), they were asked to search journals reporting educational research. They reviewed articles published mainly between 1970 and 1973 in the *Journal of Educational Psychology*, the *Journal of Experimental Education*, the *Journal of Educational Research*, and various journals for teachers such as *The Mathematics Teacher*. No experiment involving deception was found in the journals for teachers, but in the other journals experiments involving deception, lack of debriefing, and other ethical questions were located. Because of the small sample of the literature as compared to the sampling by Menges (1973), no quantitative data are reported here. It is sufficient to say that a dozen or so experiments were found that would have been included in a sampling

procedure such as that used earlier by Menges.

While direct comparisons of the 1970-1973 period cannot be made with the earlier period reported by Menges, it is clear that deception and other similar issues have not disappeared from the literature searched. In fact, not one of the dozen articles reported included any discussion of possible ethical problems related to the experiments.

The main purpose of this comment is to ask whether editors should require a discussion of ethical as well as technical aspects of experimental procedures. If graduate students can identify articles for which such discussion was needed but was lacking, should responsibility for such a discussion be left to reviewers (as was the case for all journals except one, as reported by Menges)? Should APA, as a body, advise editors of APA journals on this question? Should not the articles in APA journals model the behavior held up as standards in official APA statements of ethical principles?

Of course, journals not sponsored by APA have no obligation to adopt APA standards. But what is the obligation if an editor of a non-APA journal is himself a member of the APA?

For articles relating to the ethics of experimentation, if frequency of appearance in the *American Psy-*

chologist is a measure of our concern, then have we done all we should in encouraging authors and editors of other APA journals to report and discuss debriefing and other procedures when appropriate?

The students in our seminar were not surprised about the experimental procedures themselves but were surprised that neither authors nor editors saw fit to report the safeguards or conferrals with colleagues that might have been employed. The students made no judgments concerning the ethics of deciding to perform the reported experiments because authors did not include the reasons for their decisions nor how they arrived at them. In many cases, however, the students did doubt that the experiments were important enough to offset the ethical questions left dangling.

Knowledge begets success. This Lockheed tool begets knowledge.

The published work of thousands of the world's best scientific brains can be as close as your fingertips. With Lockheed's Dialog retrieval system, the titles and summaries of their work can be examined for as little as \$10 a search.

Psychological Abstracts alone has 125,000 abstracts. And it's only one of Dialog's many major data bases. Others cover educational research (ERIC) and exceptional children (CEC).

In minutes, Dialog can help you keep from reinventing the wheel. Or pinpoint published work that you can use as a springboard for your own achievements.

Dialog is easy to use. It only takes a terminal and a telephone. And it only takes a letter or a phone call to get more information. Contact Barbara Ellis, (415) 493-4411, Ext. 45635, Dept. 15-50, Bldg. 201, 3251 Hanover St., Palo Alto, Ca. 94304. In Washington, D.C., phone R. Caputo, (202) 872-5971; in New York, R. Donati, (212) 682-4630.

See Dialog at the 1974 American Psychological Association Convention in Atlanta.

Keller's Personalized System of Instruction: An Appraisal

Bruce A. Ryan, author; *Foreword* by Fred S. Keller. Offers the reader an objective assessment of the relevance of behavior theory, the role of unit tests, the appropriateness of the student proctor, and the success of self-evaluation in this increasingly popular approach to college-level education. In addition to an analytical review of the current literature, future directions for PSI are proposed and an invaluable "how-to" bibliography is included 1974. 32 pp. \$2.

City and State:

PLEASE PRINT (CLEARLY) NAME BELOW FOR VISIBLE LOCATOR

Title	Last Name	First Name	Initial
-------	-----------	------------	---------

This card and these fees are only applicable for advance registration prior to August 1, 1974. After that date advance registration cards received in the APA Central Office will be returned and those wishing to register will have to do so on site in New Orleans. If possible use this card rather than photocopied forms. Use another card for additional persons who wish to register. Additional cards can be obtained in any issue of the *American Psychologist* from April through July.

PLEASE COMPLETE BOTH SIDES OF THIS FORM

Convention attendees are urged to register for the meeting in advance. Not only will advance registration assist APA in planning for the meeting but advance registration represents a saving to the registrant. At its January 18-20, 1974, meeting, the APA Council of Representatives approved the following registration fees for the 1974 Convention:

For Those Registering in Advance Prior to August 1, 1974:

\$30-Nonmember

\$20-APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

For Those Registering On-Site in New Orleans:

\$35-Nonmember

\$25-APA Member, Fellow, Associate, Foreign Affiliate, High School Teacher Affiliate

Send completed form and check for registration fee to:

American Psychological Association
1200 17th Street, N.W., Room 601
Washington, D. C. 20036

Make checks payable to APA.

List of divisions for Question 1 on registration form:

- 1 - General, 2 - Teaching, 3 - Experimental, 4 - Evaluation and Measurement, 5 - Physiological and Comparative, 6 - Developmental, 7 - Educational, 8 - Social and Personality, 9 - SPSSI, 10 - Psychology and the Arts, 11 - Clinical, 12 - Consulting, 13 - Industrial, 14 - School, 15 - Counseling, 16 - Philosophical, 17 - Public Service, 18 - Military, 19 - Adult Development and Aging, 20 - Engineering, 21 - Rehabilitation, 22 - Consumer, 23 - School, 24 - Philosophical, 25 - Experimental Analysis of Behavior, 26 - History of Psychology, 27 - Community, 28 - Psycho-pharmacology, 29 - Psychotherapy, 30 - Hypnosis, 31 - State Psychological Association Affairs, 32 - Humanistic, 33 - Mental Retardation, 34 - Population, 35 - Psychology of Women.

TO ACCOMMODATIONS. Please complete and return this form to the American Psychological Association, 1200 Seventeenth Street, N.W., Room 601, Washington, D.C. 20036. Please include the name, address, and type of

accommodation as soon as possible. The address shown at bottom of page to insure desired accommodation. Convention rates DEADLINE August 1, 1974.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions. Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the Journal, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this Journal may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness. Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

Copyright © 1974 by the American Psychological Association, Inc.

Subscriptions: Subscriptions are available on a calendar-year basis only (January through December). Nonmember rates for 1974: \$12 domestic, \$13 foreign, \$2 single issue. Write to Subscription Section, APA Reprints. Authors may order reprints of their articles from the printer when they receive galley proofs. **Back Issues and Back Volumes:** For information regarding back issues or back volumes write to Order Department, APA. **Microform Editions:** For information regarding microform editions write to any of the following: Johnson Associates, Inc., P.O. Box 1017, Greenwich, Connecticut 06830. University Microfilms, Ann Arbor, Michigan 48106, or Princeton Microfilms, Princeton, New Jersey 08540. **Change of Address:** Send change of address notice and a recent mailing label to the attention of the Subscription Section, APA, 30 days prior to the actual change of address. Undelivered copies resulting from address changes will not be replaced; second-class mail is not forwarded unless subscribers notify the local post office in writing that they will guarantee second-class forwarding postage. Published monthly in one volume, 12 issues, by the American Psychological Association, Inc., 1200 Seventeenth Street, N.W., Washington, D.C. 20036. Printed in the U.S.A. Second-class postage paid at Washington, D.C., and additional mailing offices.

Executive Officer

KENNETH B. LITTLE 1200 Seventeenth Street, N.W. Washington, D.C. 20036

The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

APA Revises Its Publication Manual

ANITA DEVIVO *American Psychological Association*¹

© 1974 United Feature Syndicate, Inc.

This month APA publishes a new edition of the *Publication Manual*, the first revision since 1967. The new *Manual*, a year in preparation, replaces the familiar green-covered 1967 *Manual*. It incorporates suggestions of authors, editors, psychology department chairs, students, typists, printers, and publishers who use the *Manual* most frequently, and reflects the experience of the APA journal staff in preparing more than 2,000 manuscripts a year for publication. As an expanded second edition, it is a timely, comprehensive handbook for students of psychology, and for psychologists (and perhaps other social scientists) who write for publication.

A guide for the preparation of manuscripts is a long APA tradition. The first one appeared as a 7-page article in the *Psychological Bulletin* in 1929 when APA had 893 members. It was written by a committee of editors and managers of scientific journals for the National Research Council and was intended for science writers in general. The guide bluntly states:

The writer who is incompetent in spelling, grammar, or syntax should seek help. . . . A badly prepared manuscript always suggests uncritical research and slovenly thinking [Conference of Editors, 1929, p. 58].

Four subsequent guides more specifically addressed APA journal authors. These appeared in 1944 (a

32-page article in the *Bulletin*); in 1952 (a 60-page supplement to the *Bulletin*); in 1957 (a separate publication); and in 1967 (a separate publication). The title *Publication Manual* was first used in 1952.

As with the original guide, writing the *Manual* has continued to be a joint venture. Journal editors authorized John Anderson and Willard Valentine to prepare the 1944 instructions. The editors themselves undertook the writing of the 1952, 1957, and 1967 manuals, with Laurance F. Shaffer as coordinating editor. The new second edition is largely the combined writing efforts of the APA journal office, Susan Bunker in particular; and APA members Charles Cofer, Robert Daniel, Frances Dunham, Walter Heimer, and William Mikulas working as a task force of the Publications and Communications Board.

Why a Manual?

E. B. Strunk remarks in the closing pages of *Elements of Style*: "If one is to write, one must believe—in the truth and worth of the scrawl, in the ability of the reader to receive and decode the message [Strunk & White, 1972, p. 77]." One of the ways readers receive and decode printed material is through the conventions that grow out of usage: capital letters in important places, italics in special places, quotations in small type, lists in a column, footnotes at the bottom of a page. The conventions increase in number and complexity for readers of scientific literature who learn to expect orderly citation of references, and common forms

¹ Anita DeVivo is executive editor of APA's journals and directed the revision of the *Publication Manual*. Copies of the new 136-page *Manual* are available for \$3 from APA. Orders of \$15 or less must include payment unless they are submitted on institutional purchase forms.

for abstracts, tables, figures, and mathematical display.

The purpose of a publication manual is to record and sometimes establish such conventions so that authors, editors, and printers may refer to it as a manuscript moves from typewriter to printing press. Editors and reviewers filter a manuscript for stylistic problems that might affect content. Technical editors copy-edit for clarity of expression, for consistency of style within a journal and within the literature, and for consistency with printing requirements.

This continuing function of the APA Publication Manual is impressive when APA's journal publishing efforts at the time of the first guide are compared with the present volume of publication. In 1929, APA published 4 primary journals containing 200 articles selected from an unknown number of submissions. Today, APA publishes 14 journals, which in 1973 contained 2,500 articles selected from 6,000 submissions. The population that received the 1929 guide was around 900. The population that received the 1967 Manual was 300,000. In sheer economic terms, manuscripts that follow the instructions of the Publication Manual are handled more quickly, cost APA less in editing and printing dollars, and authors less in alterations. In terms of communication, articles published according to the

Manual give a consistency and authority to APA literature, and meet readers' expectations of quality in the printed word.

DIFFERENCES BETWEEN EDITIONS

Authors who are familiar with previous editions of the Publication Manual will note in the new edition some changes in emphases as well as points of style. The Foreword states that the Manual "recognizes alternatives to traditional forms." Some examples of breaks with tradition are new requirements for metrication and the loosening of formal expression. In the chapter on writing style, authors will find that "I" and "we" are often acceptable substitutes for the traditional third-person, passive voice construction (It was found that . . .). Consistent with its trend toward simplification, the Manual eliminates unnecessary underlines (in an a, b, c series for instance), brackets, and other devices that are more ornamental than functional. A summary of such changes appears below.

In format, the new edition is designed for authors and typists. Examples appear in typewriter type, and a complete manuscript illustrates the chapter on typing. Proofreader's marks, a checklist of common oversights, and model reference citations are placed for easy access. All material is numbered and cross-referenced.

Summary of Changes in the Second Edition of the APA Publication Manual

Publication Policies

1. Authors may no longer request early publication.
2. Authors are responsible for depositing any material for auxiliary publication. APA no longer performs this function.
3. The *Journal of Experimental Psychology* will be published in sections in 1975.

Manuscript Organization

1. Article title and by-line no longer carry footnote numbers.
2. Authors now supply cover sheets and running heads.
3. An appendix is occasionally acceptable.
4. Nonretrievable references cited in the manuscript are listed in a new "Reference Notes" section.

Manuscript Preparation

1. Some journals now require three copies of a manuscript.
2. Some journals now employ blind review procedures.

Style

1. *Webster's New Collegiate Dictionary* (1973) is the authority for spelling and abbreviation.
2. The abbreviations *S.*, *E.*, and *O.* are no longer used in APA journals.
3. Metric units are used.
4. Statistical presentation used in the *Journal of Experimental Psychology* is now used in all journals.
5. In displayed equations, equation numbers are enclosed in parentheses, not brackets.
6. The letters (a), (b), and (c) in a series are not underlined.
7. The source of a quotation is cited in parentheses, not brackets.
8. Rules are to be used in tables only when necessary for clarity.

References

1. References include only retrievable material.
2. Arabic numerals are used exclusively in reference lists.
3. Volume numbers appear in italic rather than bold-face type.
4. The form of reference citation is simplified.

Differences in style from page to page of a journal are distracting and confusing. To avoid the possibility of error, APA will continue to publish articles in the present style until the end of 1974. All manuscripts to be published in 1975 will be copy-edited to conform to the new second edition. Starting in 1975, manuscripts that depart significantly from the new Manual will be returned to authors for adjustment.

CHANGES BETWEEN REVISIONS

Changes between revisions of the Publication Manual cannot always be anticipated. They may occur in APA policy, printing requirements, or in psychology itself. Users of the new Publication Manual can refer to the *American Psychologist* for change notices that will be keyed to the Manual. Notices will be issued as necessary and listed in the AP's Table of Contents and annual Volume Contents for readers who need a comprehensive review.

Conclusion

Before the revision of the 1967 Manual started, APA invited suggestions from psychology department chairs. The new Manual incorporates two of their suggestions as appendixes—one on the preparation of student papers, and another listing 71 non-APA journals who indicated to APA that they use the Publication Manual (see Appendix). In acknowledging this broader population of users,

the Manual increases its influence on the preparation of future psychological literature. Even as this influence grows, publishers are seeking economically feasible means to continue to produce the significant literature. Ironically, while students learn the disciplines of style for printed articles, more and more psychologists are learning to use microform and data banks. As Strunk observed:

The language is perpetually in flux: it is a living stream, shifting, changing, receiving new strength from a thousand tributaries, losing old forms in the backwaters of time. To suggest that a young writer not swim in the main stream of this turbulence would be foolish indeed, and such is not the intent of these cautionary remarks. The intent is to suggest that in choosing between the formal and the informal, the regular and the offbeat, the general and the special, the orthodox and the heretical, the beginner err on the side of conservatism, on the side of established usage. No idiom is taboo, no accent forbidden; there is simply a better chance of doing well if the writer holds a steady course, enters the stream of English quietly, and does not thrash about [Strunk & White, 1972, p. 76].

The Publication Manual is based on the certain logic of converting typewritten manuscripts to traditional printed forms. As such, it becomes a model for future guides dealing with alternative forms of publication, and ultimately, I suppose, a third edition of the Publication Manual.

APPENDIX

Non-APA Journals Using the APA Publication Manual

Although the *APA Publication Manual* is intended for authors writing for APA journals, many related journals instruct their authors to refer to the Manual in preparing their manuscripts. Some journals recommend the entire Manual, and others recommend only

the reference style. The following list includes the names of some non-APA journals using the Manual at the time the second edition went to press. These journals have indicated that they plan to use the second edition.

Albert, Peter, and John B. Watson

MARY COVER JONES *University of California, Berkeley*¹

I was first introduced to John B. Watson at a lecture, which included motion pictures, in New York City in 1919. I had gone from Vassar College to New York for a weekend and was steered, more or less accidentally, by a friend to this lecture, rather than to the usual Friday night theater.

John Watson's lecture and movies reported his observations and experiments at Johns Hopkins University and set forth his proposition that there were three basic emotions present at birth—fear, rage, and love—that were called out by *specific* but limited stimuli. More elaborate emotional responses were learned by association, or conditioning. To demonstrate his thesis, Watson chose 11-month-old Albert (according to Watson, "a child with a stolid and phlegmatic disposition") as the subject of his conditioning experiment. As is well known, a loud sound, which called out the fear response, was coupled with Albert's positive response of reaching interestedly for a white rat of which he showed no fear.

After several associations of the startling sound with the presentation of the rat, Albert not only withdrew in fright from the rat but the negative reaction to the rat eventually persisted without reinforcement of the loud sound. As far as we know, this was the first laboratory attempt to condition an emotion in a child. Transference had also occurred to a white rabbit, to other furry objects, and even to a Santa Claus mask with a white fuzzy beard (Watson & Watson, 1921)!

The possibility of using the learning approach in the modification of behavior appealed to me. If fears could be built in by conditioning, as Watson had demonstrated, could they not also be removed by similar procedures?

I believe I was the last graduate student fortunate enough to work with Watson. (If there is any value in having me here today, it is to illustrate how events may shape lives.) This is how it came about: Watson was by that time in exile from Johns Hopkins University and was associated with the J. Walter Thompson Advertising Company in New York City. I was a graduate student at Columbia. Not to be suspected of trading on the sensationalism of this period in Watson's life, in the following account I quote from Watson's (1936) own autobiographical statement to indicate how his move from Baltimore to New York occurred:

1919 [was] my last full year at Hopkins. At this time, my infant work was in full swing. . . . All of this work came abruptly to a close with my divorce in 1920. I was asked to resign. . . . I got my first business tryout with the J. Walter Thompson Company. . . . This [was in the] Fall of 1920, the whole of the trying time when I was front-page news in Baltimore [p. 279].

R. S. Woodworth (1959), in a memorial statement at the time of Watson's death, said of this episode: "Misfortune overtook Watson in the shape of a sensationally publicized divorce suit [p. 302]."

Rosalie Raynor Watson, his second wife, who figured in the divorce suit, was a Vassar classmate and a friend of mine. It was through our association that I had the opportunity to work with her husband.

And so we come to Peter. It has always been of the greatest satisfaction to me that I could be associated with the *removal* of a fear when I came in contact with this three-year-old in whom a fear of animals was already well established (Jones, 1924). I could not have played the role of creating a fear in a child, no matter how important the theoretical implications. When my own children came across the case of Peter in their college textbooks, they too were relieved to find that I had functioned in this benign capacity in the psychological experiments with children and children's fears. Watson (1924a) also underscored this point in a lecture included in his book *Behaviorism*: "Finding that emotional responses could be built in with great readiness

¹This article is a slightly revised version of a paper presented at the First Annual Southern California Conference on Behavior Modification, Los Angeles, October 1969.

[Albert], we were all the more eager to see whether they could be broken down, and if so by what methods [p. 132]."

The patient, meticulous, painstaking procedures used in the experiments with Peter reflect the careful methodological style of John B. Watson, who faithfully followed Peter's progress, reverses, and final freedom from his fear. Watson paid us a professional visit on most Saturday afternoons throughout the conduct of the therapeutic sessions.

This brings us to John B. Watson himself, founder of the school of behaviorism in the United States. In 1913 Watson issued what Woodworth (1959) called the "behaviorist manifesto." The study of behavior was not only to be free from the domination of consciousness but was to take entire possession of the field of psychology (Watson, 1913). The manifesto initiated rebuttals from classical psychologists. Titchener, a member of the traditional school, published a critique in 1914, but very fairly described the positive side set forth by Watson as "the working out of general and specific methods for the control of behavior, the regulation and control of evolution as a whole [p. 3]." It is primarily this aspect of Watson's doctrine that interests the present-day behavior modification movement.

Other professional antagonists have been less kind, less fair, less understanding. Henry Murray (1960) accused Watson of having seized upon Pavlov's formulas, "[labeled] it 'behaviorism,' and sold [it] to all but a few American psychologists as the only model on which to build a . . . science [p. 6]."

As graduate students at Columbia University, my husband, Harold E. Jones, myself, and other members of our student group were among those to whom Watson "sold" behaviorism. I can still remember the excitement with which we greeted Watson's (1919) *Psychology from the Standpoint of a Behaviorist*. It shook the foundations of traditional European-bred psychology, and we welcomed it. This was in 1919; it pointed the way from arm-chair psychology to action and reform and was therefore hailed as a panacea.

Had Watson stayed in the psychological laboratory, I am sure that his theoretical position would have become more dynamic, more mellow. He would have modified an oversimplification of his concept of native disposition in view of more complex aspects of human development and functioning that were coming to his attention in our studies.

He saw my own daughter in our home, placidly playing through a loud sound that he expected would cause a traumatic response, just as it had to Albert, alone in a strange situation (Watson, 1924a, footnote, p. 121). The conclusions based on observations published by Jones and Jones (1928) could have been his: Children tend to show timidity or fear of the unexpected and unusual; and fears develop when the individual knows enough to recognize his inadequacy to cope with a strange or sudden experience.

And what about Watson as a person? Henry Murray (1960) expressed one point of view when he called him "that persuasive, one-tracked, charismatic, timely publicist [p. 6]." But for many years Watson had been a respected experimental psychologist, and, as late as 1924, though he labeled Watson's behaviorism "crude," Titchener (1914) considered a paper by Watson (1924b) in *Psychological Review* to be "[one of] the most important of the year [Larson & Sullivan, 1965, p. 348]." Angell, a former associate of Watson's when he was at the University of Chicago, though unfriendly to his behavioristic views, nevertheless stated: "For much of his actual work I have very high regard, as I have for him personally [Larson & Sullivan, 1965, p. 342]."

In his autobiography, Watson was apologetic about two books that were published after he left the academic field, *Behaviorism* (1924a) and *Psychological Care of Infant and Child* (1928). But his ability to acknowledge imperfections was an admirable quality that should recommend him to us. Referring to these two books, he said: "*Psychological Care of Infant and Child* was another book [in addition to *Behaviorism*] I feel sorry about . . . because I did not know enough to write the book I wanted to write [Watson, 1936, p. 280]." This is the book for which generations of mothers, including my own, have flayed Watson. He himself quoted one parent, "a dear old lady," who said, "Thank God, my children are grown and that I had a chance to enjoy them before I met you [Watson, 1928, p. 69]." The following is one reason for the distress that mothers expressed. Watson advised: "Never hug and kiss them [children], never let them sit on your lap. If you must, kiss them once on the forehead when they say good night. Shake hands with them in the morning [Watson, 1928, pp. 81-82]."

Watson was admirable in his willingness to criticize himself. He was also generous in giving credit

to others far beyond the professional requirements. He would not coauthor my papers because, as he said, his name was well known, and I still had my reputation to make. He wanted me to have all the recognition. In his book *Behaviorism*, he wrote: "While I spent considerable time as consultant and helped plan the work, Mrs. Mary Cover Jones conducted all of the experiments and wrote up all of the results [Watson, 1924a, p. 132]."

His expression of gratitude and appreciation to fellow scientists sounds like a roll call of the prominent names of the period: Titchener, Angell, Yerkes, Dunlap, J. McKeen Cattell, Adolph Meyer, Lloyd Morgan, and Edward Thorndike, to mention just a few. A remark in reference to a period of sleeplessness and anxiety in Watson's university graduate days may come as a surprise to those who see him in juxtaposition to Freud: "It . . . prepared me to accept a large part of Freud, when I first began to get really acquainted with him around 1910 [Watson, 1936, p. 274]."

Watson was magnanimously appreciative of his contemporary scientists. He also regularly and publicly acknowledged financial support, even including that munificent sum of \$100 contributed by the American Association for the Advancement of Science for his work with infants, which gave us, among other outstanding contributions, the case of Albert.

You may have noted that I have never assumed a first-name basis in talking of John B. Watson. Our relationship was more formal than not. This may be due to the custom at that time for contact between colleagues, especially in the student-teacher relationship, to remain impersonal. Watson regularly addressed his colleagues in correspondence by their last names—as Dear Yerkes or Dear Titchener (Larson & Sullivan, 1965). I never lost the feeling of awe that I had for Watson, the scientific innovator. It would have been very uncomfortable for me to have called him John. This

may be only a reflection on professional style in the 1920s, but I suspect it tells you something about our respective personalities as well.

A discussant of Watson's school of behaviorism said: "The strength of the movement lies not in its fundamental logic but in its laboratory performance [Larson & Sullivan, 1965, p. 348]." It is this aspect of Watson's contributions with which I am most identified and which I most appreciate.

We now use the term *behavior modification therapy* to describe the practical approach of John B. Watson and his followers. I welcome this opportunity to acknowledge with gratitude our indebtedness to this impressive figure in American psychology.

A Taxonomy of Instrumental Conditioning

PAUL J. WOODS *Hollins College*¹

The history of science contains numerous instances whereby a classification schema has proved to be of value in organizing our knowledge of the world (e.g., see Hall & Hall, 1964, pp. 95-108). Various taxonomies have been developed in the biological sciences for classifying plants and animals; in chemistry the periodic table of the elements is a prime example which illustrates not only the organizational value of such a system but its *discovery value* as well. Before Mendeleeff arranged the elements according to their atomic weights, the discovery of new elements had been essentially "accidental." The classification by atomic weight, however, allowed the known elements to be grouped into families provided that empty cells were left in the table. Mendeleeff not only successfully predicted that elements would eventually be discovered to occupy these empty spaces but he also was remarkably accurate in predicting many of the properties of these yet-to-be-discovered elements (Cragg & Graham, 1954, pp. 28-31).

For the most part, classification schemes in other sciences have dealt with "things" having physical properties, such as plants, animals, rocks, basic elements. Classifications based on *operations*, however, as have been evolving in the psychology of learning (Grant, 1964), are not without precedence (e.g., see Serfass, Steinhardt, & Strong, 1950). Furthermore, there seems to be no logical reason why the rules for classificatory schemes cannot be applied to experimental operations (Cohen & Nagel, 1934, pp. 241-244).

In their classic work *Conditioning and Learning*, Hilgard and Marquis (1940) described four types of instrumental conditioning procedures: reward training, escape training, avoidance training, and secondary reward training. In their notes following the chapter on instrumental conditioning, they pre-

sented a historical summary of the distinction between classical and instrumental conditioning and an additional discussion of the above four types. In retrospect, it seems somewhat curious that they considered secondary reward training as a separate type rather than as simply another way to use the reward training paradigm itself. (It is also interesting to note how far back some of this work extends. As early as 1910, for example, Glaser reported using an escape paradigm to motivate rats in maze learning.)

In his revision of Hilgard and Marquis' *Conditioning and Learning*, Kimble (1961) also discussed reward and avoidance training but considered escape training to be a subvariety of avoidance. In addition, he noted another variation of the avoidance paradigm in which the exteroceptive "warning" stimulus is omitted (cf. Sidman, 1953a, 1953b). Kimble (1961) then introduced two new categories of instrumental conditioning: (a) one in which "a specified response would lead to the non-occurrence of a positive reinforcer" and (b) one in which "it would lead to the occurrence of a negative reinforcer [p. 70]." For each of these categories, Konorski (1948) reported that an organism learned a response that was *antagonistic* to the one called for by the experimental paradigm. In the first of these two new categories, the organism received a positive reinforcer for *omitting* or failing to emit a specified response. Thus, Kimble termed this "omission training." The second category was punishment training in which a response was followed by an aversive event. Although Hilgard and Marquis (1940) discussed this, it was not included as a type of instrumental conditioning because they considered it a "method for the elimination rather than the acquisition of a response [p. 74]."

The next advance was made by Grant (1964), who introduced the first true classification scheme and, in the process, illustrated its discovery value as well. He suggested a classification based on three dichotomous dimensions. (a) whether there was a "cue to impending reinforcement", (b)

whether the response was "positive or negative," by which he meant *emitted or omitted*; and (c) whether the "reinforcement" was a "reward or punishment." All possible combinations of these dichotomies resulted in eight categories of instrumental conditioning. In Grant's scheme, escape training appears again as a separate category rather than as a subvariety of avoidance, as Kimble (1961) had treated it. Furthermore, discrimination training, which was treated in separate chapters by both Hilgard and Marquis (1940) and Kimble (1961) and not discussed as another type of instrumental conditioning, now takes its place *within* Grant's scheme. But even more important, Grant's classification generated two additional logical possibilities, which apparently had never been studied in the laboratory, although examples cited by Grant from everyday situations appeared quite feasible. Grant (1964) termed these new types "discriminated punishment training" and "discriminated omission training."

Yet, there was still something missing. The newest scheme had no place for the, by then well-known, unsignaled, or Sidman avoidance, paradigm nor did it allow for another obvious possibility, "signaled escape." In this paradigm, an exteroceptive signal informs the subject whether the escape response will result in "relief" from the aversive stimulation to which he is exposed. Evidence that this is a real paradigm for laboratory studies has been reported (Davenport, 1970; Davenport &

Eschenbrenner, 1970; Davenport & Leiner, 1968; Woods, 1973b). To deal with these problems and to attempt to improve on the classification scheme and thus, possibly, clarify our thinking, it is proposed that Grant's third dimension be modified. Rather than referring to "rewards and punishments," the modification incorporates "positive or desirable" stimulus consequences and "negative or aversive" stimulus consequences and, furthermore, provides that each of these consequences can be either "presented or increased" in magnitude or intensity or, conversely, "removed or decreased" in magnitude or intensity. With these additional considerations, we can then generate the classification scheme shown in Figure 1.

As can be seen, each cell or operation is unique and is described by four characteristics. Also, it is important to note that the classification scheme is exhaustive, including as it does all possible combinations of these characteristics. Later in this presentation, each operation is dealt with in more detail. For the present, to help familiarize the reader, I will consider several of the cells briefly. Cell 1A, for example, defines the conditioning paradigm in which the *emission* of a response is followed by the *presentation* of an *unsignaled* stimulus event which is *positive or desirable* to the organism. This is recognizable as the common paradigm of reward training. Likewise, Cell 1D describes escape conditioning: An *aversive stimulus* is removed or decreased in intensity following a

		CONSEQUENT STIMULUS EVENT UNSIGNALLED		CONSEQUENT STIMULUS EVENT SIGNALLED	
		Operation performed on stimulus event			
		Present or increase	Remove or decrease	Present or increase	Remove or decrease
STIMULUS EVENT CONTINGENT UPON RESPONSE EMISSION	Positive or "desirable"	IA	IB	IIA	IIB
	Negative or aversive	IC	ID	IIIC	IID
STIMULUS EVENT CONTINGENT UPON RESPONSE PREMISSION	Positive or "desirable"	IIIA	IIIB	IIIA	IIIB
	Negative or aversive	IIIC	IIID	IIIC	IIID

Figure 1. A taxonomy of instrumental conditioning.

specified response, and there is no signal to forewarn of the outcome. Finally, at this point, we can consider a paradigm in which a signal gives the organism information ahead of time as to the consequences of his behavior. In all of these cases the *absence* of the signal means that the same behavior will not be followed by any consequent stimulus events. Take Cell IIA: If a response is emitted in the presence of a particular cue or following a particular stimulus, then a positive event or a reward will follow, and the reward will be presented if and only if the response occurs when the signal or some cue is present. These are the operations we have traditionally used to teach a *discrimination*.

For the moment, let us return to some general considerations. That the present scheme does not represent merely a symmetrical extension of Grant's (1964) classification can be seen in Table 1, which indicates his types as well as a proposed nomenclature for the newly generated and old familiar paradigms. As can be seen, Grant's classification included all four of the present A cells, none of the B cells, three of the C cells, and only one of the D cells.

The proposed nomenclature has been generated on the basis of the assumption that it is desirable in science to be systematic and consistent and to use a terminology that has some communication

value. Indeed, the proposed labels for each paradigm not only indicate the relationships among the various types of conditioning but, by themselves, they also indicate fully the response requirement and the operations to be performed without any further need for definition or explanation. (Such a nomenclature scheme has an advantage similar to the one used in organic chemistry, where a compound's name denotes its molecular structure.) While it must be admitted, in this connection, that it is perhaps more colorful to refer to one of our basic learning paradigms as "Sidman avoidance," it is certainly not defensible on any grounds other than a wish to honor Sidman.

It has been assumed that some terms can be left out in order to ease communication. In their absence, however, the operation is meant to be "understood." For example, if the paradigm is not labeled as *signaled*, it is understood to be *unsignaled* without our having to say so. Likewise, paradigms in Groups I and II require a response to be *emitted* without explicit specification. In the third term of the nomenclature, *penalty* is introduced to describe the removal of desirable stimuli and *escape* has been changed to *relief*. This change follows from the assumption regarding the value of being consistent: That is, the experimenter arranges for the delivery or administration of a reward, a penalty, or a punishment; he does not administer an *escape*. He

TABLE 1

The Relationship between Grant's (1964) Classification and the Present One with a Proposed Nomenclature

Paradigm	Instrumental types listed by Grant	Proposed nomenclature		
			Reward	Conditioning
IA	Reward training			
IB				
IC				
ID	Punishment (or passive avoidance conditioning)		Penalty	Conditioning
	Escape training		Punishment	Conditioning
		Relief		Conditioning
IIA	Discriminated operant	Signaled	Reward	Conditioning
IIB		Signaled	Penalty	Conditioning
IIC		Signaled	Punishment	Conditioning
IID		Signaled	Relief	Conditioning
IIIA	Omission training	Omission	Reward	Conditioning
IIIB		Omission	Penalty	Conditioning
IIIC		Omission	Punishment	Conditioning
IIID		Omission	Relief	Conditioning
IVA	Discriminated omission training	Signaled	Omission	Conditioning
IVB		Signaled	Omission	Conditioning
IVC		Signaled	Omission	Conditioning
IVD		Signaled	Omission	Conditioning
	Avoidance conditioning		Relief	Conditioning

can, however, administer *relief*, a seemingly more appropriate term to use.

It should be noted that this classification scheme does conform to the general requirements cited by Cohen and Nagel (1934, p. 242) for an ideal classification: (a) A division must be exhaustive; (b) the constituent species of the genus must exclude one another; (c) a division must proceed at every stage upon one principle, the *fundamentum divisionis*.

Descriptions of the Specific Paradigms

With this general, overall introduction let us now turn to a more detailed consideration of each paradigm. The operations for each paradigm can be more clearly seen and kept in mind with the help of symbolic figures. The letter S will denote the antecedent signaling stimulus; R will denote the response; and + and - will signify desirable and aversive consequent stimulus events, respectively.

Then  (with time represented along the horizontal dimension) will denote the occurrence of signals and responses;  will be used to indicate that a response was omitted or not made at a particular point in time. Finally, \uparrow will denote a presentation or increase and \downarrow , a removal or decrease in the magnitude or intensity of the consequent stimulus events. Thus, simple reward conditioning would appear as follows:

PARADIGM 1A: REWARD CONDITIONING

This is the most familiar and most common form of instrumental conditioning and, as such, really needs no further elaboration. Described before the turn of the century by Morgan (1894) and by Thorndike (1898), it is the basic paradigm of the free operant procedure (Skinner, 1938). It has been used in literally thousands of studies (see Table 2).

PARADIGM 1B: PENALTY CONDITIONING

This paradigm can be represented as follows:

This common form of punishment was not included in Grant's classification nor has it received much experimental attention. A procedure used by Weiner (1962), however, appears related. Human subjects had the task of monitoring a display in a signal detection situation. "Points" were awarded for correctly detecting a signal, but in some conditions it *cost* the subject points to observe the display. Since points, albeit learned both by instruction and prior social conditioning, are positive or desirable stimulus consequences, such a procedure could be used more widely in studying this paradigm.

Even though learning researchers have hardly touched upon this paradigm, it is often used in everyday life; traffic fines, yardage loss in football, time in the penalty box in ice hockey, and imposed fines following conviction for a crime are familiar penalties. In the area of child rearing a mother might send her child's playmate home because of a squabble, thus penalizing both children by removing social companionship; also a parent might take away such desirable things as hammers, drums, horns, etc., because of what the child was doing with them.

PARADIGM 1C: PUNISHMENT CONDITIONING

This paradigm (passive avoidance) can be represented as follows:

This was one part of Thorndike's original *law of effect* (the other part being Paradigm 1A):

Of several responses made to the same situation . . . those which are accompanied or closely followed by discomfort

to the animal, other things being equal, will have their connections with that situation weakened, so that, when it recurs, they will be less likely to occur [Thorndike, 1911, p. 744].

Extensive research then caused Thorndike subsequently to question the *weakening effect* of such stimuli, which he termed "annoyers." It was not that such stimuli could not suppress behavior, for they could. Rather, what was questioned was the notion of the weakening of "connections" between situations and responses. It was subsequently shown, for example, that when an aversive consequence is removed, the response which it had suppressed will return and continue under conditions of extinction for just as long as it would have had it never been suppressed by punishment in the first place (Estes, 1944).

With all of these paradigms, if the response requirement is not met, then no stimulus consequences will follow. That is, in this case, if the animal does not respond it will not be punished. This fact led to the use of the term *passive avoidance*. In retrospect, from the present analysis, the establishment of a nomenclature based upon the failure of a paradigm is not the clearest or most desirable course to follow (or, at least, we should be consistent and call reward training, for example, "passive nonreward training").

In real-life situations, from the treatment of pets and children to the treatment of criminals and foreign nations, one could hazard the cynical guess that this learning paradigm is more frequently used, by far, throughout all aspects of human interaction. When some person, group, or nation does something that some other person or group in power does not like, then aversive consequences will be delivered, ranging from verbal chastisement to execution and war. Since this is so familiar to all, no further examples are necessary.

PARADIGM ID: RELIEF CONDITIONING

This paradigm (escape training) can be represented as follows:

For an aversive stimulus condition to be established in intensity it obviously must exist in the first place. In an experimental situation we "establish the motivating conditions" by subjecting the animal to an aversive situation without allowing him the possibility of preventing such an exposure. Then, he is given control over the consequent reduction of the aversive intensity. Many of the published studies using this paradigm manipulated the intensity of an electric shock which the animal's response was then allowed to terminate (e.g., see Boren, Sidman, & Herrnstein, 1959; Kaplan, 1952; Trapold & Fowler, 1960). With this procedure, however, we can discern a serious confound: The amount of relief is directly related to the original shock level, and, hence, the contribution of either one of these variables to any performance differences cannot be ascertained. A procedure that avoids this confound was first reported by Campbell and Kraeling (1953) and was subsequently studied extensively by the present author and his students (e.g., see Woods, 1973a; Woods, Davidson, & Peters, 1964; Woods & Holland, 1966). One general finding from this work is that when the original level of aversive intensity is held constant and increasing amounts of relief are made to follow the response requirement for different groups, then the differential performance that occurs is very similar to that which follows increasing amounts of positive reinforcement in the reward conditioning paradigm. That is, when analogous operations are manipulated in these rather different paradigms, similar behavioral changes occur. Such generality is encouraging and the extent to which it occurs deserves further study. That it is limited, however, has recently been suggested by a study of the partial reinforcement effect in relief conditioning (Woods, Markman, Lynch, & Stokely, 1972).

Humans perform many responses to escape from aversive situations in everyday life: turning down a radio that is too loud, adjusting the thermostat when the room is too hot or too cold, leaving an area that is permeated with obnoxious odors, walking out of a dull or upsetting movie, leaving a group in which the conversation is being dominated by a boor, taking an aspirin for a headache, resting when fatigued, and taking a vacation to "get away from it all." Even at more complicated levels we can discern the basic relief paradigm. A citizens' group, for example, might initiate legal action against an industry that was polluting the environment, or people might campaign against an incumbent poli-

ucian they disliked. All of these are clear illustrations of responses being performed in order to reduce or eliminate aversive situations.

PARADIGM IIA: SIGNED REWARD CONDITIONING

This paradigm (discriminated operant) can be represented as follows:

In all signaled emission paradigms, information regarding the stimulus consequences is given to the organism prior to the performance of the relevant behavior. In effect, another restriction is imposed on the if-then condition. In the unsignaled emission paradigms the consequences will follow if and only if the response is made. Here, however, the consequence follows if and only if the response is made when and only when the signal is present.

To add a signal to the reward conditioning paradigm is a simple and logical extension. In a free operant, lever-press situation with rats, for example, food pellets will be delivered for lever pressing only when a signal light is lit. Such conditions were demonstrated quite some time ago (Skinner, 1933, 1938). However, as noted in the introduction, discrimination training was often considered as a separate phenomenon in learning rather than as a variety of instrumental conditioning. Historically (Yerkes & Watson, 1911), it was a technique for studying sensory thresholds in animals. It then played a prominent role in early theoretical controversies between Gestalt and stimulus-response positions (e.g., see Krechevsky, 1932, 1938; Spence, 1936, 1937, 1938). It was also studied as a logical step following the establishment of the phenomenon of "generalization." Generalization, responding to new stimuli that are physically similar but perceptively different from the original training stimulus, was studied as a phenomenon in its own right, mostly in the framework of classical conditioning (Kimble, 1961, pp. 329-330), although instrumental responses also were used (e.g., Grandine & Harlow, 1948). Of course, trying the same response to similar stimuli is clearly an adaptive

strategy with great survival value. (No two apples are identical, but most are edible.)

In summary, then, discrimination has been considered either as a separate phenomenon or as a secondary one to generalization. It was not until Grant's (1964) scheme that it found a logical place within instrumental conditioning paradigms, and, of course, it continues to hold an integral place within the present scheme.

A commonly used procedure for establishing a discrimination in the laboratory is to combine the basic paradigm of rewarding responding to the "correct" stimulus with Paradigm IIC (described below), which consists of punishing responses to the "incorrect" stimulus. Such combinations are also common in everyday life. If you drive through a green traffic signal, you are rewarded by getting to your goal; if you drive through a red one, you may be punished with a summons or an accident. If children laugh and play during recess, they are rewarded by friendly reactions from peers; if they laugh and play during class, they are punished by the teacher. If one laughs at a joke told in a group, he is rewarded by social approval from the group; if one laughs at a sad story told by the same individual, he is punished by social disapproval and made to feel embarrassed. If a girl smiles at a boy, he knows that approach responses will be reinforced; if she gives him a "cold stare," he knows that approach responses will be punished.

PARADIGM IIB: SIGNED PENALTY CONDITIONING

This paradigm can be represented as follows:

Just as with unsignaled penalty conditioning, this paradigm was not included in previous treatments of instrumental conditioning and to the best of our knowledge has not been reported in the experimental literature.² In everyday life, however, such

² It appears appropriate to make a point here that will apply to our discussion of a number of these paradigms. A search of the world's literature for instances or examples of the less well known paradigms is really not feasible be-

situations are bountiful. Whenever there is a "warning" that attempts to constrain certain behaviors where the consequences will be a monetary fine, we have an instance of the signaled penalty situation. All sorts of traffic signs are signals that if a particular behavior occurs, the individual will be fined: "speed checked by radar," "school—15 mile limit," "driver subject to arrest for throwing litter from vehicle," "no parking," "car will be towed away at owner's expense," etc.

**PARADIGM IIC: SIGNED PUNISHMENT
CONDITIONING**

This paradigm (discriminated punishment) is represented as follows:

This heretofore unstudied paradigm was generated by Grant's (1964) classification scheme. Grant provided an illustration of this paradigm with a description of a colleague whose speech was "colorful" in informal social gatherings but whose undergraduate lectures were "models of propriety." ("Colorful" speech in the latter context would, presumably, have resulted in the punishment of severe criticism or even dismissal.) He also described the procedure of punishing his cats for scratching the furniture only to have them learn not to scratch the furniture in his presence; that is, they learned that punishment would occur only under the signaled condition of his presence.

Examples of this paradigm are easy to generate: The familiar "wait till your father gets home!" is

a warning signal to the child that if certain behaviors continue he will be spanked by the "old man." Likewise, ignoring a "beware of the dog" sign may result in being bitten, and hunting on posted land may lead to a charge of buckshot from a farmer. The paradigm plays a prominent role in many child-rearing situations in which the parent is the signal. The child learns that many behaviors, sexual, aggressive, verbal, etc., will result in punishment if performed in his mother's presence.

PARADIGM IID: SIGNED RELIEF CONDITIONING

This paradigm can be represented as follows:

This is a simple logical extension of what has traditionally been called *escape training*. A signal merely informs the subject in advance whether the relevant instrumental response will result in successful escape or relief. This paradigm, however, was not one of those generated by Grant's classification, and it has received no experimental study until recently. Davenport and Eschenbrenner (1970) and Davenport and Lerner (1968) have used this paradigm, and they report varying degrees of success. A clear demonstration of its reality has been more recently reported by the present author (Woods, 1973b). Rats swam in a cold-water alley tank to a separate goal tank, which on relief trials was warmer and on nonrelief trials was the same temperature as the alley. At the beginning of each trial, a light signal informed the animal whether the goal tank would be warmer. The animals did learn to swim with greater vigor and fewer competing reactions on those trials in which relief was signaled.

Outside of the laboratory, in everyday situations, illuminated "exit" signs are obvious signals for escape in case of fire or other emergency. And who has not anticipated relief by following a sign to the rest room?

A friend beckoning from the hallway can be a signal one can follow to escape from a boring meeting. When someone is lost in the wilderness, rescuers use signals to guide them to safety, and

cause the terminology by which information is stored and retrieved has not been consistent nor readily translatable. For example, what is referred to below as "omission reward conditioning" has been labeled by people working in the free operant tradition as a "differential-reinforcement-of-other-responses" schedule. This is not meant to criticize their choice of terminology; it is merely intended as an explanation for our inability to be absolutely certain as to whether any particular paradigm has been empirically studied and reported. The author would welcome, therefore, communications citing any instances of what we currently believe to be unstudied paradigms.

sailors in fog or distress respond to signals in a similar manner.

PARADIGM IIIA: OMISSION REWARD CONDITIONING

This paradigm (omission training) can be represented as follows:

The first full description in English of this procedure apparently was in Konorski (1948, chap. 12), but the term *omission training* itself did not appear until Kimble (1961). Konorski's work dealt with simultaneously established classical and instrumental responses. In this case, a salivary response in dogs was classically conditioned to a metronome. Then, occasionally, at the same time the metronome was activated, the dog's leg was passively flexed. On these trials food was omitted, while on trials with the metronome alone and no leg flexion, food was continued. The animal's reaction to this was not only to resist the flexion but to actively *extend* his leg in so doing. What is reported, then, is not mere omission but the actual strengthening of an antagonistic response: Whether or not such a reaction is a characteristic of all omission paradigms is an important matter, yet to be determined.

In describing some real-life instances of this paradigm it is easy to see how an antagonistic response may often be involved. The familiar expression of "biting one's tongue" testifies to this: One cannot just *omit* a verbal response but must go one step further to an antagonistic reaction.

In order to stay in old Uncle Harry's will, you must not tell him what you really think of him. Such constraints may result in an exaggerated display of affection. A mother might say to her children, "If you don't argue and fight I'll take you out for ice cream." Their reaction could very well be profuse displays of affection. A teacher might tell her class that if they do not talk during the reading period she will organize their favorite game during recess. Again, overly strong efforts at remaining silent might result.

A behavior modification technique in which someone is given monetary rewards for not smoking is

another example of this paradigm. And, finally, parents might resort to this in attempts to control their financially dependent adolescent children. "Don't talk to your father that way! Who do you think is putting you through college?" Translation: Omission of angry critical responses will result in continued financial support.

PARADIGM IIIB: OMISSION PENALTY CONDITIONING

This paradigm can be represented as follows:

In this paradigm we find the case in which someone is penalized for not doing something. As with many of the remaining paradigms it does not yet seem to have been studied in the laboratory.

In real-life situations most penalties are probably the consequence of something an individual *does*, but there are still clear examples of penalties for failing to respond. If you fail to lock your car, it may be stolen; likewise, a fine is the consequence for not returning a library book on time, and late payment fees are often the sanction for not paying bills when they are due. (Our own APA resorts to this procedure; it costs a member \$5 if dues are not paid before December 1 each year.)

Parents seem more likely to manipulate rewards and punishments rather than penalties, but we can conceive of some child-rearing illustrations. In the area of "manners" or "social graces," a child might have something taken away for failing to make a particular response. For example, if a child does not say "thank you" when he is given some candy, he might then have that candy taken away.^{*}

* A subtle but important distinction between a *penalty* and a *reward reduction* should be made for terminological clarity. By *penalty* we want to refer only to the removal of positive stimuli that the individual already has in his possession. Reductions in anticipated rewards, then, are not penalties. If the child's next allowance, for example, is cut down because of something he did or did not do we have a reward reduction (à la Crespi, 1942) within a reward conditioning paradigm.

PARADIGM IIIC: OMISSION PUNISHMENT CONDITIONING

This paradigm is represented as follows:

Given our cultural zeitgeist, this is probably one of the more common omission paradigms. We tend to resort to punishment as a consequence for someone failing to react in an expected manner just as we resort to punishment for "undesirable" or obnoxious actions. Also, in many cases, what we term *neglect* results in aversive consequences as a direct result of our failure to act without any intervention from others. If a worker, for example, fails to put on safety glasses or other necessary protective devices, he may suffer bodily injury. If we fail to check the gauge, we may run out of gas; if we fail to check the tires, and hence do not discover the soft one, we may be stranded with a flat; and if we fail to carry out preventive maintenance, the car may not start. When you leave home, you fail to confine the pets, with the result that they damage the furniture.

But, as mentioned above, other people often do intervene to administer punishment for response failure. Children are scolded for not washing, for not straightening up their rooms, for not wiping their feet, for not saying "thank you," etc. If one fails to arrive at work on time, one may be "chewed out" by the boss, and if a student fails to study, he or she may receive an F on a test. Many examples can easily be generated, and it should be clear that this is a commonly used paradigm in everyday life.

But what of laboratory work? This has actually been investigated for over 20 years, but its location in this classification scheme is probably going to come as a surprise to many researchers in this field. We will argue that this truly is the paradigm for what has come to be known as Sidman avoidance (after Sidman, 1953a, 1953b). Since the argument, however, also applies to the more common form of avoidance, we will take it up below under that paradigm (Paradigm IVC).

PARADIGM IIID: OMISSION RELIEF CONDITIONING

This paradigm is represented as follows:

As mentioned in discussing Paradigm ID, in order for "relief" to follow as a consequence of responding, the organism must be in an unpleasant condition to start with; this is no less true in the case of response omission. Here we are talking about the reduction of some aversive state being the consequence of the withholding of some behavior. Again, as far as we can determine, this has not been studied in the laboratory, although real-life illustrations do appear valid. If you stop smoking, various unpleasant side effects such as coughing may go away. (Of course, aversive withdrawal symptoms may also follow as a consequence, which would be omission punishment conditioning, but this merely illustrates that several paradigms can operate simultaneously.)

If you do not socially react to a boor, he may leave. If you do not laugh and applaud a friend's rather bad home movies, he may stop showing them sooner.

The consequences of muscle relaxation procedures (Jacobson, 1964) can fall into this paradigm in those cases in which the individual is suffering pain, as in a tension headache. By relaxing, which is the cessation (omission) of muscle-tensing reactions, the individual experiences the consequences of relief from the pain.

And, for a final illustration, we should be able to agree that, unfortunately, some school situations are aversive for many children; when the children are allowed to leave school on time for *not* running and shouting or talking in class, then we have another instance of omission relief conditioning.

PARADIGM IVA: SIGNED OMISSION REWARD CONDITIONING

This paradigm (discriminated omission training) can be represented as follows:

This is the other "new" paradigm generated by Grant's (1964) classification scheme, and he likened it to seeking "the appearance of virtue rather than virtue itself [p. 13]." He then discussed it with an example par excellence concerning a parent who offers to reward his daughter with money or other valuables if she stops smoking, drinking, swearing, or some other such behavior. The young lady, who was maintaining the behavior at a high operant level, interprets the bargain to mean that she should not get caught, and she develops a well-discriminated omission. She continues the behavior but is just careful not to do so in the presence of her father or a likely informant.

Another general class of common animal training procedures should suffice for illustrating this paradigm: Using food rewards, dogs are trained to obey certain commands, and whenever the response requirement consists of the termination (omission) of any behavior we have this paradigm. For example, "stay" commands the dog to not follow, and if this is strengthened with food or petting, the procedure is that of signaled omission reward conditioning.

PARADIGM IVB: SIGNED OMISSION PENALTY CONDITIONING

This paradigm can be represented as follows:

This is another paradigm uncovered by the present scheme, and so far as it can be determined it has no research history. As discussed in the section on Paradigm IIIB, most penalties seem to be the consequence of action rather than inaction, although we can develop some illustrations that argue for the existence of this paradigm.

With the stop sign at the corner as the signal, then failure to stop can result in a fine. A fine also could result if you fail to stop when signaled to do so by a policeman. And a parking ticket is often the result of failing to heed the overtime signal on a meter.

We can also conceive of a situation in which the stock market is dropping and a broker advises a stockholder to sell; the advice is the signal. But the stockholder *fails* to sell with the consequence that the value of his stock declines. Hence, we again have a penalty for failing to respond to a signal.

PARADIGM IVC: SIGNED OMISSION PUNISHMENT CONDITIONING

This paradigm (avoidance conditioning) can be represented as follows:

If the organism does not respond to a signal, he will be punished; hence, if the designated response is made, the punishment will be *avoided*. As mentioned above, in the discussion of Paradigm IIIC, the location of avoidance conditioning in this scheme will most probably come as a surprise to many researchers in this area. Those who have considered escape and avoidance to be very similar, such as Kimble (1961) and Denny (1971), may be surprised to see that these paradigms differ on three of the four dimensions in the present classification; the only thing in common is that they involve aversive events. But probably the most surprise and possibly the most controversy will be generated by the classification of avoidance conditioning as an omission paradigm. This is because we have long emphasized the active nature of the subject in the avoidance situation with the resulting puzzle as to how an action can be maintained by no consequences. Hilgard and Marquis (1940) emphasized this direction long ago when they said:

Learning in this situation appears to be based in a real sense on the avoidance of the shock. It differs clearly from other types of instrumental training in which the conditioned response is followed by a definite stimulus change—

food or the cessation of shock. In instrumental avoidance training the new response is strengthened in the absence of any such stimulus; indeed, it is strengthened because of the absence of such a stimulus [pp. 58-59].

Our traditional view of avoidance is understandable, but we hope that a reassessment of this position will not meet with great resistance. Viewing it as an omission procedure causes us to see the avoidance response itself as an antagonistic response to the one called for by the paradigm. Then, as such, avoidance appears related to omission training and punishment training in which antagonistic responses have also been reported (Konorski, 1948). The proposed nomenclature in which avoidance is called "signaled omission punishment conditioning" reflects the similarity of these paradigms.

Attempts to explain avoidance conditioning have taxed our theoretical creativity. Miller (1935) explained it in terms of fractional anticipatory goal reactions (r_g 's). These anticipatory reactions to shock were seen to increase in intensity as the actual shock itself approached, leading to a heightened state of tension. By running in the other direction, say, the animal is able to relieve this tension. Tension relief is drive reducing, and hence the puzzle of avoidance is explained by this theory as a form of escape conditioning.

Subsequently, more eloquent theories were developed (Mowrer, 1947; Solomon & Wynne, 1954). In these, two processes were seen as being involved in the explanation of avoidance learning. First, in the early stages of learning a neutral stimulus, the signal, being paired with a noxious shock, was seen as acquiring through classical conditioning procedures the capacity to elicit fear. Then the second process, that of establishing the avoidance response itself, was again seen as an instance of escape conditioning with fear reduction being the reinforcement for the avoidance response. Thus, buzzer and shock, say, occur in sequence until the buzzer itself elicits fear; at this point the animal makes a response which both reduces the fear and avoids the shock.

But matters are certainly far from settled regarding theoretical explanations of avoidance, and the area continues to receive considerable attention (e.g., see Brush, 1971; D'Amato, Fazzaro, & Etkin, 1968; Hoffman, 1966; Sidman, 1966). Any further discussion of theoretical positions in this area is beyond the scope of the present article. I merely wish to point out that theoretical concerns might take a different direction if avoidance is viewed as it is classified here. Avoidance, whether

signaled or not, is really very similar to punishment as has been tacitly recognized when the latter has been referred to as "passive avoidance." Given this recognition one wonders why there has not been the same degree of empirical and theoretical concern for the punishment paradigm. Apparently, we do not find it as much of a puzzle or challenge to understand why an organism would fail to respond in order to avoid punishment as we do to understand why an organism would respond to avoid punishment. But let us look more closely at what does happen in the punishment situation. Initially the organism has been making a response such as approaching the food cup at the end of an alley. Then the situation is changed so that approach to the food cup results in an electric shock. It does not take many experiences like this before the organism "pulls itself up short," so to speak, after it has started down the alley. Further, it is common for us to observe the animal engaging in other behaviors that compete with the approach behavior. What this argument is suggesting is that in passive avoidance the organism may not be passive at all, but, indeed, may be engaging in active responding in order to avoid the punishing goal box. If one agrees with this analysis then one is agreeing that punishment conditioning is very similar to avoidance conditioning.

In any case, when punishment is the consequence of a response requirement, the organism will typically fail to meet that response requirement. In punishment conditioning an *emitted* response is the requirement for aversive consequences, and that response will be *omitted*. In avoidance conditioning a particular response must be *omitted* for aversive consequences, and that response will thus be *emitted*.

In real life we do many things merely because and solely because not doing things would result in punishment. Some students study because if they did not they would fail; soldiers salute superior officers because if they did not they would be disciplined; drivers keep their eyes on the road because if they did not they would crash; children wipe their feet because if they did not their parents would scold; and, in some cases, professors keep their office hours because if they did not students would complain and the dean would call.

PARADIGM IVD: SIGNED OMISSION RELIEF CONDITIONING

This paradigm can be represented as follows:

S

R

+

-

This final paradigm is also one that appears not to have been studied in the laboratory, yet, as before, we can consider some real-life illustrations that argue for its existence. If a person who is suffering from the effects of heavy smoking responds to "Warning: The Surgeon General Has Determined That Cigarette Smoking Is Dangerous to Your Health" by ceasing to smoke, then we have signaled relief for response omission.

Other medical illustrations also seem to fit nicely here; this paradigm is operating whenever a person is advised (the signal) that he or she will obtain relief from some distress by *not* doing certain things. Dealing with someone who is overweight provides a good concrete example. Being overweight has unpleasant consequences, and relief is obtained by following a physician's advice not to eat high-calorie foods. Likewise, the aversive effects of tension and stress are relieved by following advice to stop certain stress-producing activities.

Some Final Observations

There is one point that is terminological and procedural yet relevant to the proposed taxonomy in that it will demonstrate how the system can handle a dominant feature of contemporary research, namely, schedules of reinforcement. In reward conditioning, for example, when the stimulus consequence called for by the paradigm does indeed occur, we have by definition a "rewarded" trial. If the experimenter arranges, however, for the paradigm to fail, that is, prevents the expected stimulus consequence, we have a "nonrewarded" trial. We can generate, therefore, any schedule of reinforcement by intermixing these two possibilities. Various schedules of reinforcement, then, do not represent exceptions or additions to the present classification; they can be incorporated within it.

Still along these lines, if we switch to the paradigm "failure" possibility for 100% of the trials, we establish thereby the conditions for "extinction." This is a well-known manipulation in reward con-

TABLE 2

A Tabulation of Instrumental Conditioning Studies Cited in Psychological Abstracts

Instrumental paradigm (traditional name)	% of studies reported each year		
	1961 (N = 245)	1966 (N = 607)	1971 (N = 580)
Reward training	40.8	36.7	42.1
Discriminated operant	33.9	28.5	28.1
Avoidance conditioning	7.0	9.9	8.3
Punishment	1.2	5.4	7.1
Escape training	.8	1.5	2.2
Combinations of two of the above	4.9	9.6	5.5
Instrumental paradigms combined with classical conditioning	4.9	2.5	1.2
All other instrumental paradigms and combinations	6.5	5.9	5.5

ditioning, and this scheme suggests that the same manipulation with other paradigms might be a fruitful avenue for research. It can also be suggested that subsequent operations analogous to the reinforcement shift studies in reward conditioning would be worthwhile in other paradigms. (This has been done, e.g., with relief conditioning: Woods, 1967; Woods, 1973a.) Another research direction that should be expanded is one in which certain combinations of the basic paradigms are used in the same experiment. Such a development, which has already seen some limited application, might establish experimental situations that are more analogous to "real life." Parents, for example, frequently reward their children for a response that is made and punish them if the response is not made (a combination of Paradigms IA and IIIC).

In closing, it might be illuminating to get some idea of the distribution of our research efforts in these areas. We have, therefore, classified all of the basic learning studies that appeared in *Psychological Abstracts* for 1971 and for 5 and 10 years before that.⁴ The results, which are somewhat striking but perhaps not surprising, are shown in Table 2. A very few paradigms have dominated our research efforts in instrumental conditioning. One strategy for the future is to break the "iron grip of tradition" and explore the operational manipulations suggested here. Do learned changes

⁴ The author wishes to thank Virginia T. Scott for her help with this tabulation.

in behavior occur with all of these and, if so, do analogous manipulations lead to similar or different phenomena? In a conclusion to a discussion of scientific psychology in transition, Kimble advised:

If anything should be abandoned for the time being, it is the experimental strategy that allowed me in my doctoral dissertation (Kimble, 1947) to investigate eyelid conditioning at six intervals between 0.10 and 0.40 seconds with substantial numbers of subjects at each point. We need to worry more about the magnitude of effects and the generality of our laws [Kimble, 1973, p. 18, italics added].

Such generality should be investigated not only across species and apparatus but across operational manipulations as well.

A Curriculum for the Teaching of Behavior Assessment

IAN M. EVANS *University of Hawaii*

ROSEMERY O. NELSON *University of North Carolina at Greensboro*¹

Banned from Soviet Union schools by the Central Committee of the Communist Party in 1935, burned by the school board in Houston, Texas (Nettler, 1959), and frequently harangued by the general public (see Lovell, 1967), psychological tests have not met with universal affection. In behavior modification the cry is "don't test, teach," and of the 168 psychotherapists polled by Meehl (1960), only 17% felt that testing was of much value to them. Advocates of objective psychometric testing conclude from the available literature that projective tests are "unreliable, nebulous, and invalid" (Eysenck, 1970), whereas Mischel (1968) argued that neither projective nor psychometric tests "have served very usefully as indirect signs of internal predispositions [p. 145]." Meanwhile, back in the internship training centers, the most frequently used and most heavily emphasized test in training is the Rorschach (Garfield & Kurtz, 1973), and although often exposed to the critical literature, students in academic training programs continue to be taught tests like the Rorschach and the MMPI, perhaps, as Breger (1968) suggested, to fulfill professional role expectancies.

A more constructive teaching plan might concentrate on procedures that are evolving as alternatives to typical psychological testing. In clinical training programs with a predominantly behavioral orientation, it is particularly incumbent upon the critic of traditional assessment to provide an approach that dovetails, in both theory and practice, with the general principles being taught. The present authors were independently faced with the task of teaching assessment as a first course to graduate students in behaviorally oriented clinical programs.² In a recent discussion we discovered that our approaches were strikingly similar, and although none of the parts was uniquely original, it seemed worthwhile to report the whole. There is surprisingly little discussion of course content in

graduate clinical education compared with, for example, teaching methods, program goals, or the likelihood of the graduates ever receiving gainful employment. It might also be of interest to practicing psychologists to know what contemporary clinical students are able to offer if they balk at administering test batteries or pronouncing on a projective protocol.

One challenge in constructing an assessment course is to reconcile the skills required for the student's clinical work in the immediate future with a critical faculty needed to appreciate both the limitations of assessment and the corrective steps possible. Given such a goal, neither descriptions of specific tests nor intricate psychometric issues received much attention. The concepts of reliability and validity were naturally omnipresent, but utility was heavily stressed. Nelson chose Mischel's (1968) *Personality and Assessment* as her textbook. Evans referred extensively to Mischel's monograph, but selected as a text the British publication edited by Mittler (1970), *Psychological Assessment of Mental and Physical Handicaps*. These two texts were not on face value the most

¹We are grateful to Marvin R. Goldfried for allowing us to examine the syllabus of the assessment course taught at the State University of New York at Stony Brook.

Requests for reprints should be sent to Ian M. Evans, Department of Psychology, University of Hawaii, 2430 Campus Road, Honolulu, Hawaii 96822.

²Differences in our respective clinical programs resulted in somewhat different course structures. Evans was fortunate in being able to teach the course after the students had had detailed exposure to the methods of behavior observation of Roland G. Tharp. Nelson included in her course a certain amount on standardized intelligence, screening, and achievement tests; we have not included this in the course description, but the orientation was in line with the course as a whole. Nelson's course was linked to a practicum, whereas at Hawaii the practicum accompanied only Tharp's section of the two-semester course.

compatible of partners, but within the organization of the course they complemented each other well. The organizing principle was the single-subject research model, which integrated both the empirical study of psychopathology and the experimental analysis of individual behavior control and modification.

Behavior Assessment and Psychopathology

The present authors considered it important to teach behavior assessment within the context of psychopathological research. There are two justifications for this, and they overlap, in essence, with the two major alternatives to the medical model of psychiatric disorder: the sociopsychological and the defect models. The defect model will be discussed later. Sociopsychological perspectives were provided by reference to Braginsky, Braginsky, and Ring (1969), Goffman (1961), Plog and Edgerton (1969), Sarbin (1967), Szasz (1961), and Ullmann and Krasner (1969). The weight of this reading assignment was reduced somewhat by the students having had, as expected, exposure to these ideas as undergraduates.

With the backdrop of a sound understanding of the entire labeling process, the student still needed to attend to aspects of the current action on the clinical stage. A minimal classificatory scheme seemed necessary for students to order their experiences, and they may have noticed, with some sense of relief, that a major part of Ullmann and Krasner's (1969) study was organized around the traditional psychiatric nosology. Some familiarity, therefore, was required with the *Diagnostic and Statistical Manual* (1968) of the American Psychiatric Association, and with any of the more empirical psychiatric texts (e.g., Freedman & Kaplan, 1967; Slater & Roth, 1969; Storrow, 1967).

At some time in the future, students would have to label patients for institutional or legal purposes, or simply to communicate with other mental health professionals. In response to a questionnaire, however, 53% of the University of Hawaii clinical students indicated that in field settings they had been obliged to provide formal diagnostic labels and they reported that the demand had come from a secretary. Students seem to have their own way of dealing with the mental health bureaucracy: More than half of the students claimed that under

this stricture they typically selected the least offensive label possible, usually *adjustment reaction*.

There are, of course, alternatives to sabotage. The least satisfactory was to attempt to improve upon the notorious unreliability of diagnostic categories (e.g., Beck, Ward, Mendelson, Mock, & Erbaugh, 1962; Schmidt & Fonda, 1956; Zigler & Phillips, 1961; Zubin, 1967). Brief mention was therefore made of diagnostic checklists (e.g., Overall & Gorham, 1962; Rimland, 1968), decision-making flow diagrams (e.g., Nathan, 1967), and the use of objective tests (e.g., Cattell, Schmidt, & Bjerstedt, 1972). Cattell et al. chastised clinicians for not using these tests since they possess "diagnostic certitude that decidedly exceeds that by other methods [p. 240]"—cold comfort for those challenging the utility of the whole categorical system.³

A second possibility was to reform the classificatory model and to relate classification to experimentally determined mechanisms of behavior. The most systematic efforts in this direction were made by Eysenck (1960) in his simple but brilliant insistence on dimensional rather than categorical organization. As a strategy, Eysenck's approach was appealing to the students. Enthusiasm was somewhat dampened when it was admitted that despite its promise for the future, the approach had virtually no current clinical utility. It is true that Eysenck's personality theory is the only one to have a strong relationship to behavior therapy (Eysenck, 1957; Eysenck & Rachman, 1965), but at the moment, its relevance to the planning of treatment is extremely tenuous—the few nonexperimental examples given by Eysenck (1970) notwithstanding.

What Eysenck (1957) called "rational" assessment leads to the second major reason why behavior assessment should go hand in glove with psychopathological research. Eysenck (1960) described abnormal behavior as "the defective functioning of certain psychological systems [p. xii]." Following this model with some license, assessment for treatment becomes the delineation of the underlying deficits (or handicaps) in the behavioral repertoire of the patient. The single-subject research strategy which carries this out is discussed in the next section.

³ To be fair, Cattell is no admirer of current diagnostic categories. For many years he advocated the use of personality source traits, a strategy which in many ways is similar to Eysenck's.

What needs to be mentioned here is that assigning a descriptive label to a patient should immediately put the clinician in touch with the experimental work that has been conducted with respect to that syndrome. From the many examples given to the students, we can select two widely divergent ones: (a) Describing a child as autistic should focus attention on difficulties of processing sequenced perceptual input (Hermelin & O'Connor, 1970); (b) in working with an obese patient, the external food stimuli regulating his eating might be more profitably considered than either his oral fixations or his attempts to reduce anxiety (Schachter, 1971). A student cannot be expected to be *au fait* with every new finding, but he can be expected to recognize the current experimental literature as one area from which to draw his hypotheses concerning a patient.

The deficit model need not be exclusively concerned with physiological disturbance, although it is especially appropriate in cases of probable organic pathology and childhood handicaps. Staats (1968), for example, suggested that a reading disability might be a function of deficiencies in a more basic response mechanism (i.e., visual attention) or in the child's motivational system, or both. A good illustration of his theory applied to assessment was recently furnished by a University of Hawaii graduate. E. S. Kubany (1971), in his doctoral dissertation, produced experimental evidence that reinforcing performance on a standard attainment test had a greater effect on the persistence of Hawaiian children than on the Caucasian children (see also Edlund, 1972). When testing children in his clinical practice, Kubany manipulated social reinforcement, nonsocial reinforcement (e.g., toys, candy, or money), and social criticism to observe the effects on behavior, after which recommendations were made regarding the teaching style that might be used most profitably with the child (Kubany & Sloggett, 1973a).

The Single-Subject Research Strategy

In traditional assessment a patient is usually described with reference to a preconceived theory or model of personality and abnormality. The present authors' concern with experimental psychopathology is of a quite different nature—economy of effort. Research findings are neither infallible nor immutable, and they provide a guide to, not a substitute for, the detailed idiographic analysis of the precise variables relevant to the target be-

haviors of the individual patient. Shapiro (1951, 1957) was one of the earliest proponents of the view that this analysis should adhere to the rules of scientific evidence. He argued, rather neatly, that one does not test the patient but the hypotheses about the patient, and he emphasized that psychiatrists typically do not formulate their diagnostic questions in the form of testable hypotheses. Shapiro wrote a number of articles on this approach, the most comprehensive of which appeared in 1966.

Required reading for the course participants also included the surprisingly few case studies where the use of ad hoc tests had been carefully carried out (some collected in Davidson & Costello, 1969; others cited in Mittler, 1970). Hamilton's (1964) criticism of the impracticality of the method was also recommended, as well as Tizard's (1971) critique of Mittler (1970), and an entertaining paper by Gwynne Jones (1971) that discussed the general issues surrounding idiographic research.

One of the examination questions asked the course participants to compare and contrast Shapiro's experimental approach with a functional analysis in the Skinnerian sense. The logic of the two is essentially the same, although there is, of course, an obvious difference in research methodology. Just as different problems in fundamental psychology require different research methodologies for their investigation, so do different problems in applied psychology; formal hypothesis testing is not the only rigorous strategy (cf. Shapiro, 1952) within the intensive research model (Chassan, 1960). Behavior assessment may begin with the free observation of behavior and its covariation with environmental change, successful intervention in that environment being confirmation of the hypothesized functional relationship. Exclusion of other possibly relevant factors is achieved by additional manipulations, sometimes of the stimulus antecedents (e.g., Evans, 1971; Lovaas, Freitag, Gold, & Kassorla, 1965), but more commonly of the response consequences.

In the course discussed here, therefore, attention was paid to the single-subject research designs typically used in behavior modification. Examples abound in the *Journal of Applied Behavior Analysis*, but useful summaries can be found in Baer, Wolf, and Risley (1968); Bijou, Peterson, Harris, Allen, and Johnston (1969); Browning and Stover (1971); Gelfand and Hartmann (1968). For a more sophisticated discussion, Sidman (1960) was recommended. At the same time it was pointed out that

control techniques like baseline reversals, multiple baselines, differential reinforcement of another response, and so on, have serious limitations when it comes to the broad *evaluation* of therapy or remedial training (Evans, 1971). In addition, one must decide on the significance of the observed changes. Gentile, Roden, and Klein (1972) have suggested that the analysis of variance model is fitting.⁴ Also, a key assumption of these strategies is that noncontingent reinforcement will not maintain behavior, but there is evidence in operant conditioning literature that this is not invariably the case (Schoenfeld, Cole, Lang, & Mankoff, 1973), so we expect that orthodox, applied, operant research designs will themselves soon be modified.

A second difference between the two single-subject models was the concern for organismic variables (Mittler, 1970) as opposed to the controlling environmental stimuli, both antecedent and consequent (Mischel, 1968). Those with a Skinnerian bent have tended to ignore, even denigrate, intra-individual causes of behavior dysfunction; those concerned with individual deficits often underplay the force of environmental circumstances. Integrating these two assessment styles provides an objective clinical method of wide generality and power. It is ideally tailored to the planning, guidance, and evaluation of behavior modification (therapy), and so it was to the precise specification of assessment for treatment that the course turned.

Assessment for Behavior Change

Although the assessment procedures typically used in behavior modification are more narrow than the possibilities encompassed by the intensive single-case strategy advocated in the course, a reasonably specific technology for obtaining samples of behavior has been worked out in recent years and students should be familiar with it. The guiding

tenets of behavior assessment were most comprehensively laid down by Mischel (1968): (a) Behavior is a function of the environment; (b) particular behaviors are specific to particular situations; and (c) samples of behavior must be obtained by the least inferential methods. Since Mischel's evidence and interpretations have been challenged, the students were referred to some critical comments (e.g., Alker, 1972; Bem, 1972; Craik, 1969). Other discussions of the rationale of behavior assessment can be found in Goldfried and Kent (1972), Goldfried and Pomeranz (1968), and Nurnberger and Zimmerman (1970). Kanfer and Saslow (1969), one of the central references of the course, provide the best, most detailed statement of the kind of information that should be obtained in assessment. The methods by which the behavioral excesses, deficits, and assets of the patient are precisely ascertained can be broken down into two major groups: (a) interviewing and (b) the observation of behavior.

BEHAVIORAL INTERVIEW

Insofar as one can identify behaviorally the important elements of a good interview, we feel that instruction can best be given in a practicum setting following the microteaching techniques developed at Stanford (e.g., Bush & Allen, 1964). The general principles of a good interview can be obtained from any of the classic psychiatric accounts (e.g., Sullivan, 1954), but Benjamin (1969) is concise and informative. MacKinnon and Michel's (1971) study was also quite useful for more inexperienced students since it contained specific advice on handling difficult and unusual situations. Two guides were available to the kind of interview that is valuable in obtaining detailed information on child behavior problems: Holland (1970) and Wahler and Cormier (1971). To get a flavor of the research related to interviewing, Matarazzo's (1965) study was assigned, and the additional complexities of interviewing children were touched upon by reference to Yarrow's (1960) chapter discussing the interview as a research tool. Finally, to dramatize the potential limitations of the interview, we suggested the students read Labov's (1970) fascinating anecdotes of interviewing black ghetto children.

It is not the techniques of interviewing but the content and focus of the interview itself that most differentiate the behavioral interview from any other (Lazarus, 1971; Wolpe, 1970). A complete

⁴Since this article was written, Gottman (1973) has presented a useful discussion of time-series methods in $N=1$ research. Gottman's communication is specifically pertinent to this article: (a) in demonstrating that baseline shifts published in the behavior modification literature may lack statistical significance, (b) in discussing the causal inferences possible from different time-series designs, and (c) in emphasizing once again that "by monitoring a patient over time and by monitoring treatment variables simultaneously, the therapist receives feedback which aids the process of therapy and also generates hypotheses for future testing [p. 98]." Behavior therapists have made fair use of assessment devices administered repeatedly, as will be commented on in the next section.

anagnosis is not usually considered of much value in behavior therapy, and where a social history is considered desirable it is often in the form of a questionnaire (Wolpe & Lazarus, 1966) that the patient can fill in at home to save time. A detailed account, both historical and contemporary, is usually required of the problem area, for example, with sexual disorders, a thorough sexual history (Annon, 1971) and survey of experience (Bentler, 1968); with marital disharmony, a detailed analysis of the marriage (Stuart & Stuart, 1972); and with phobias, a set of questions aimed at the specific stimulus elements to be incorporated in the systematic desensitization hierarchy (Wolpe & Lazarus, 1966). All the paper-and-pencil devices that have become popular in behavior therapy are really time-saving extensions of the interview. The Fear Survey Schedule (there are now several, the first being published by Wolpe & Lang, 1964) might be used to turn up fears that were overlooked in the interview or that the patient may have considered irrelevant or embarrassing. For subsequent use in designing contingencies, the behavioral clinician often has the patient list his reinforcers (Reinforcement Survey Schedule—Cautela & Kastenbaum, 1967; Mediator-Reinforcer Incomplete Blank—Tharp & Wetzel, 1969), just as one might ask a parent or teacher to list all the potential reinforcers for a child patient.

Behavior therapists have evolved a number of similar devices that are directly related to the strategies of behavior change. In essence they involve systematization of parts of the behavior change strategy itself: (a) identifying the target behavior, (b) analyzing its functional relationship with the environment, and (c) determining possible sources of behavior influence. Most of the tests are without norms, but that is usually excused by administering them frequently and relying on the individual trend (analogous to an operant baseline) to monitor the client's progress and objectively guide the course of therapy. The utility of these methods is therefore clear and may be evaluated by the relative success of behavioral techniques. In research reports and case studies on some of these "tests," there is a growing reliance that is unwarranted in terms of proven reliability, validity, and immunity to repeated administration. Behavior therapists seem to be in the awkward position of coming to depend on tests that are less psychometrically sophisticated than those they have spurned.

DIRECT OBSERVATION OF BEHAVIOR

It is not really surprising that behavioral observation should be the parvenu of clinical assessment, considering its relative neglect in basic psychological research. The standard references for instruction in behavioral observation are the studies of Bijou, Peterson, and Ault (1968); Bijou et al. (1969); Blackham and Silberman (1971, Chapter 4); Buckley and Walker (1970, Section D); Colman and Boren (1969); and Hall, Christler, Cranston, and Tucker (1970). An ethological perspective was provided by Hutt and Hutt (1970). Various methods of recording one's observations, either directly (Wright, 1967) or by some kind of code (O'Leary, Romanczyk, Kass, Dietz, & Santagrossi, 1971; Patterson & Cobb, 1971; Werry & Quay, 1969), were also discussed.

We were interested and pleased to notice that in the Introduction to the *Standards for Educational and Psychological Tests* (APA, 1974), which, incidentally, will now become part of the required reading for the course, the Joint Committee on Revision of Standards gave tacit recognition to behavioral observation by stating, "the psychologist who counts examples of a specific type of response in a behavior-modification setting is as much responsible for the validity of his interpretations of change or the basic reliability of his observations as is any other test user [p. 4]." The many hazards of behavioral observation were presented to our students in detail; indeed there is extensive literature on matters such as the reactive nature of being observed, observer bias, and the selection of behavioral categories (a problem to which we are particularly sensitive in cross-cultural settings; see, e.g., Weiss & Gallimore, 1973). Lipinski and Nelson (in press) have reviewed this literature so it will not be listed here; needless to say, their review was required reading.

The students were taught not only to perform behavioral observations themselves but also to teach other persons in the client's environment to use this method of data collection (e.g., Kubany & Sloggett, 1973b; Tharp & Wetzel, 1969). Alternatively, especially in adult behavior therapy, the patient may have to be taught to observe and record his own behavior, usually by diaries, but also by frequency counts or by close attention to eliciting stimuli (Watson & Tharp, 1972). The unreliability and reactivity of self-recording, however, limit its potential as an assessment method (Brodin, Hall, & Mitts, 1971; Gottman & McFall, 1972; Johnson

& White, 1971; Kanfer, 1970; Lipinski & Nelson, 1974; McFall, 1970; McFall & Hammen, 1971; Simkins, 1971a, 1971b).

While observations may be made in a variety of settings, it is sometimes useful, especially for research purposes or in circumstances of common behavior deficits, to record behavior in standardized situations. A good example of this use of direct observation is the Behavioral Avoidance Test (Borkovec & Craighead, 1971; Levis, 1969), although it has rather serious measurement problems (Bernstein, 1973). Sloggett (1972) used a simulated classroom to observe certain behaviors in teachers—the children having been trained to act in appropriate as well as villainous ways. A number of groups working with alcoholics have observed and assessed their patients' drinking behavior in realistic replicas of public bars (e.g., Schaefer, Sobell, & Mills, 1971). Sobell and Sobell (1972) reported that patients are best interviewed when inebriated because the sedative effect of alcohol reduces anxiety and facilitates information gathering. Structured clinical interviews (Burdock & Hardesty, 1968a; Ulmer & Timmons, 1966) fall into this class, and checklists of behavior in given situations are logically part of these techniques, so the students were exposed to some of the more common examples; Balthazar Scales of Adaptive Behavior (Balthazar, 1971); Cain-Levine Social Competency Scale (Cain, Levine, & Elzey, 1963); Behavior Problem Checklist (Peterson, 1961); Vineland Social Maturity Scale (Doll, 1953); Ward Behavior Inventory (Burdock & Hardesty, 1968b); Hamilton Psychiatric Rating Scale for Depression (Hamilton, 1967).

Conclusion

A student who appreciates the pitfalls of psychological measurement, and whose clinical work follows the rules of applied research, should not find it too difficult to integrate into his empirical assessment strategies the mensural advances of basic research technology. The many developments of special clinical significance are so disparate and scattered that we only attempted to present a few of the more promising ones. But there are many others; for example: penile volume and pupil dilation are among the measures that have been used to gauge sexual orientation and erotic interest, despite certain limitations (Zuckerman, 1971); rate of habituation of the orienting response (Lader &

Wing, 1966) and speed of acquisition of the conditioned eyelid response (Martin, Marks, & Gelder, 1969) are possible prognostic indicators for systematic desensitization with phobias; psychophysiological measures, especially forearm bloodflow (Kelly & Walter, 1968), can be used to guide progress up the desensitization hierarchy (Mathews, 1971); operant conditioning techniques have been used in a number of assessment-related ways (Weiss, 1968), including hearing loss (e.g., Evans, 1970) and visual acuity (Macht, 1971); some behavior therapists have become interested in repertory grid measures (Bannister & Mair, 1968).

The usefulness of some of these measures in clinical practice remains to be seen; in any event it depends on the ingenuity with which the applied psychologist can adapt them to his purpose. The above references were presented mainly to stimulate that ingenuity.

Overall, the references cited in this course description represent a formidable reading list for one semester. To some extent the material has been increased by mixing rather than distilling our respective requirements; on the other hand, for the sake of brevity, we have cited reviews of papers that the students read in the original. We are not so naive as to anticipate that every participant read every reference, but we do expect most will have something better to offer their clients than a research-inspired skepticism for projective and other traditional tests.

At the beginning of this article, mention was made of the continued use of traditional assessment methods in applied settings (Garfield & Kurtz, 1973). By comparison with McCully's (1965) findings, Levitt (1973) also noted that field training directors have shifted only slightly in their belief in the importance of mastery of the Thematic Apperception Test (TAT) and the Rorschach and that, furthermore, they continue to express dissatisfaction with students' academic training in projective techniques.⁴ Our curriculum is not likely to reduce this discord, but it does offer a complete alternative to the limbo that might result from what both Levitt (1973) and Garfield and Kurtz (1973) see as a dichotomy between "research values" and "clinical expediency." Our students

⁴ We suspect that Levitt, Garfield, and Kurtz have fallen into the questionnaire trap and that assessment by direct observation would reveal a steady annual decline in the use of projective tests in clinical practice.

face, we hope, no such dichotomy. They were taught a working model for assessment—taught to be applied scientists who bring to the assessment situation knowledge of behavioral disorders, the ability to use objectively a variety of methods of measurement, and, above all, a critical respect for data in the guidance and improvement of their clinical activities.

Community Psychology and the Competent Community

IRA ISCOE *University of Texas at Austin*¹

The term *community psychology* was coined at the Boston (Swampscott) Conference on the Education of Psychologists for Community Mental Health in 1965. Although its original purpose was "to consider problems and issues in the education of clinical psychologists for community mental health activities," the conference was unanimous in its recognition of the need for American psychology to develop a wider arena for preventive mental health measures and of the necessity to study and deal with persons and communities in their natural habitats. Explicit in the recommendations of the conference was a dissatisfaction with the then existing models of clinical psychological training in terms of their suitability in preparing psychologists for the delivery of mental health services and research within community settings. The conference report (Bennett, Anderson, Cooper, Hassol, Klein, & Rosenblum, 1966) has become somewhat of a collector's item, representing a new posture for an important segment of American psychology. Numerous developments since 1965 have attested to the viability of the concept of community psychology and to the sensitivity of the conferees to the changing mood and thrust of America. Various pieces of legislation have placed the locus of treatment of broadly defined emotional disturbance within a community, as opposed to an institutional, context, and the nation as a whole has become increasingly aware of enormous unmet mental health and human growth needs.

The formation of the Division of Community Psychology in 1966 was in recognition of the shifting concern from more classical psychopathological models to "problems of living." Schizophrenia and

the neuroses pale in magnitude and locus of treatment when compared with social concerns such as violence, drug abuse, the sexual revolution, the legitimate demands of minority groups, inner-city decay, and public education, to mention but the major ones. All of these concerns reflect the psychological state of our society, and how effectively these concerns are dealt with is an index of the well-being of the nation as a whole. They serve as grim reminders that social problems will not "go away," and that the results of neglecting crucial social problems cannot be erased by crash programs or the rapid infusion of money and resources.

In beginning to deal with these problems, we recognize the blurring of jurisdictional and definitional boundaries. Traditional concepts about cities, counties, and states are undergoing realignment. Psychological rather than geographical membership is being emphasized. A safe prediction is that more problems are yet to arise. The lowering of the voting age to 18 will bring about the realignment of political power. College populations have already begun to exert much greater influences in the community, and it is only a matter of time until legal responsibility changes from age 21 to 18. This is part and parcel of the secular trend in America. Things happen earlier than they used to (and faster too). A scientifically based community psychology must be able to predict some of these developments and make preparation to cope more adequately with them. A community psychology that makes its living dealing only with the casualties of social systems will soon lose its viability. It should be proactive rather than reactive, adhering to a fundamental tenet of public health that no condition is ever prevented by treating the victims of the condition itself.

The Growth of Community Psychology

There are several indications of community psychology's continuous growth, despite its rudimen-

¹ This article is a revision of the presidential address presented to the Division of Community Psychology (Division 27) at the meeting of the American Psychological Association, Honolulu, Hawaii, September 4, 1972.

Requests for reprints should be sent to Ira Iscoe, Department of Psychology, University of Texas, Austin, Texas 78712.

tary nature with regard to definition, conceptual clarity, and levels and types of training. An increasing number of university-based programs are offering community psychology as a specialty or subspecialty. Faculty with community psychology backgrounds are in demand, and clinical psychology programs are taking on a more community mental health emphasis. Community psychology has begun to declare its ideological independence from clinical psychology and from community mental health. If tolerance for ambiguity is one of the strong indicators of good mental health, then it must be possessed in abundance by the many graduate students entering this new area.

Rather than become embroiled in definitional aspects or jurisdictional disputes, community psychology has to proceed as best it can, recognizing that it will have overlaps with other disciplines and subareas within psychology. This condition is of course not unique to community psychology. Reiff (1970) pointed out the existing paucity of applicable social science knowledge about communities, the need to develop a body of knowledge via community-based research, as well as the failure to use existing knowledge more effectively. The transfer from the laboratory of the university to the laboratory of the community is a difficult process, but one that must be accomplished if behavioral science concepts are to be tested within community settings. This need was poignantly pointed out by the late Martin Luther King in his distinguished address to the American Psychological Association in 1968. He called upon American psychologists to lend their skills in dealing with the race problem. A five-minute standing ovation and genuine goodwill on the part of the great bulk of American psychologists did not lead to constructive community activities. Perhaps American psychology was not ready to enter into the complexities of communities; indeed, as will be pointed out, psychology and behavioral sciences generally, perhaps for good cause, have not been actively included as an integral part of some of the more prominent human welfare activities in the last 10 years.

Kelly (1968, 1970, 1971) enumerated some of the tasks facing community psychologists and some of the qualities desirable in the community psychologist himself. A developing community psychology could play an important role in community research by designing effective coping methods to deal with some of the more salient social problems that are now faced or will be faced by communities in the future. The first generation of community

psychologists "emerged" at Swampscott. A new generation is just beginning to emerge. Hopefully it will bring with it the sophistication and technical competence to work effectively in community settings and to be able to discriminate between "action" and genuine change. The late 1960s were full of action. Just how much change was brought about still remains to be seen. One of the main conceptual approaches of community psychology could be the increasing of the competence of human beings in dealing with the problems they face. Characteristic of high-risk populations such as the poor, minorities, and the aged is a high degree of community disorganization and the lack of effective coping strategies. How a community is to be made more competent is an enormously complex matter, and no prescription presently exists. A consideration of the competent community, its challenges and potentialities will nevertheless be attempted.

Concepts of the Competent Community

The processes by which a community gains competence are presently very unclear and excellent topics for research. However, the concept of the competent community is not a new one. Cottrell (1964) employed it when he urged psychiatrists not to try to "take over" the then developing community mental health movement, but to work instead toward the fostering of competence on the part of consumers of mental health services and the development of new types of manpower and new concepts of treating emotional disturbance in children and adults. Many community mental health centers are under severe criticism today for failures in these very areas. Leighton et al. (1963), in their community research, pointed out that the level of integration of the community more strongly reflects its mental health than the variables of sex, age, or occupational status. The development of the competent community involves the provision and utilization of resources in a geographical or psychological community so that the members of the community may make reasoned decisions about issues confronting them, leading to the most competent coping with these problems. Coping is stressed rather than adjustment, in keeping with a positive, activist point of view. Conceptually, the competent community is one that utilizes, develops, or otherwise obtains resources, including of course the fuller development of the resources of the human beings in the community itself. In this respect, the concept of the competent community

parallels the concept of positive mental health as put forth by Lehmann (1971), who suggested that the criterion of "utilization of resources" be employed as an index of mental health rather than the criterion of absence of symptomatology. It is not the presence of problems but the manner in which they are coped with that is all important. Success in coping with one type of problem should broaden the repertoire of skills of the community and enhance its possibility of more effective coping with other problems that arise. Presently communities differ greatly in this respect. Middle-class communities have the mechanisms and the track record. They point to their successes. The lower socioeconomic strata do not have this record, nor are they integrated enough to even communicate what few successes they have. How can a community psychologist or community psychology be of help to a disenfranchised or disorganized community? This is precisely the challenge, and it involves the sailing of uncharted waters as far as psychologists are concerned. A detailed knowledge of the community itself is essential, especially its potentials. From what sources does the present leadership arise? What are the real issues? Who is trusted in the community? What changes are needed in the educational and human service delivery systems? The enormity of the problem should not detract from the potential rewards. Already some glimmerings of progress may be detected by the sensitive observer. Attempts at community controls in deprived districts and a court order prohibiting the classification of minority group children by standard intelligence tests are examples.

The community psychologist should be attuned to the phenomena that deprived communities do not always go for goals understandable to the middle-class power structure. Persons in a constant battle against poverty settle at first for immediate visible goals. As chairman of a community action program, I walked into a meeting and received loud applause from the blacks and Mexican-Americans of the audience. I thought it was for the extra money I had obtained for a summer recreation program for children. In fact, the applause was due to "negotiation" on my part that had resulted in the city rather quickly paving two streets and patching up chuckholes in some others. An increase in the number of children getting lunch at school is tangible; a revision of the curriculum for better competence in mathematics is not quite so tangible. Priorities will differ in different com-

munities, depending on their stage of development. Community psychology not only must be sensitive to where the community is but must also eventually be able to predict the next steps in its development.

Characteristics of the Competent Community

The competent community or, more specifically, persons and groups in the competent community have a repertoire of possibilities and alternatives. Their strength lies in their alternatives. They know where and how to acquire resources. Characteristic of disadvantaged communities today is not only the economic condition of the members but their psychological disadvantages, as exemplified by feelings of hopelessness and powerlessness. The community lacks "clout." It will not be heard by those in power. These communities represent perhaps the greatest single challenge to community psychology. Paradoxically, it is in these same communities that the greatest resistance to research will be encountered in the form of suspiciousness, resistance, distrust, and outright opposition. This is an unfortunate legacy from the "objective" behavioral science research of the past. Persons without hope and without power and with no trust in behavioral sciences are difficult to convince that some benefit will accrue to them or their community as a result of the research and activities being undertaken. Their reinforcement, on the contrary, has been that of being "tooled-over" by the system. The barriers are not insurmountable. Skill on the part of the community psychologists will be needed so that they may find ways of reaching and involving the populations they are working with or researching on. In a time of mounting consumerism, community psychology must be prepared to involve consumers. In doing so, community psychology has to be prepared for the results of success. Mounting feelings of hope and some power lead to demands for independence. Community psychologists must be prepared to part with populations once certain goals have been achieved or once the status of these populations has been improved. If they do not part with the populations, at least the relationships have to be negotiated taking into consideration changed conditions.

Community psychology has grown so rapidly that it is appropriate to call attention to these potential dangers now, lest it become a victim of an all too prevalent ideology that wittingly or unwittingly fosters dependency and fails to support the develop-

ment of competence of the populations and communities it is involved with. If the genuine goal of community psychology is to foster the growth of competence and independence, nothing is healthier than for all persons in a problem area to negotiate from positions of strength rather than from a condition in which there is inequality among the negotiators. Unfortunately, a good part of the helping philosophy today has not been in this direction. Research within community settings has not been of much benefit to the community. There is a cartoon somewhere in which a Southwest Indian tribe, after years of misery and exploitation, finally comes into a considerable sum of money from oil lands. Their first act of independence is to boot out the anthropologist who has been studying them, for these many years, with no visible benefits to them. It is to be hoped that an effective community psychology will arrange a smoother transition.

Another challenge for community psychology is the bringing about of a productive dialogue between the existing power structure and the emerging competent community. Failure to do so will result in violence, disillusionment, and disadvantage to both parties. This has already happened in some cases and testifies to our failures to date. An activist position without provision of an accommodation for those in power and those out of power can only result in unproductive acrimony, conflict, and polarization. A mature community psychology must help prepare persons for the assumption of responsibilities rather than merely the assumption of power.

The Competent Community, Human Service Programs, and Their Evaluation

Although many programs designed to be of assistance to the economically disadvantaged and ethnic minority groups are no longer supported to the extent that they were under previous government administrations, human service delivery systems are part and parcel of our American society. Despite the billions of dollars involved, very few funds have been allocated to research and evaluation. The reluctance of persons to evaluate their organizations and efforts is certainly not limited to human service programs. However, so marked has been this lack of evaluation and feedback that sometimes one wonders rather facetiously if there does not exist an anticompetence plot in America today. The continuation of poverty, dependency,

ignorance, and insecurity are in their long-term effects enormously destructive to human beings as human beings. It is easier and more acceptable under present procedures to administer vast programs designed to treat casualties of social systems, putting on Band-Aids forever, rather than examining the systems themselves. The areas of evaluation and research are not the unique provinces of community psychology or the field of psychology. Yet psychologists interested in behavior should find exciting possibilities—possibilities, incidentally, that might extend to the entire field of psychology. For example, the Job Corps dealt with, and still deals with, a segment of the American population that psychology knows very little about, namely, the economically disadvantaged male and female between the ages of 16 and 21. What enormous benefit to developmental psychology might have emerged if a continuing evaluation and follow-up research program had originally been tied into the entire endeavor! There is a clear, national trend toward evaluation couched in such terms as cost effectiveness, program evaluation, cost benefit analysis, zero-based budgeting, and continuity of care. Behavioral scientists (including community psychologists) must develop valid criteria for evaluations lest less valid criteria are imposed by persons from the accounting offices.

Presently, very little valid data exist to even begin to try to answer some very fundamental questions. What are the critical points of entering, remaining, and leaving public welfare? Is there a welfare generation and, if so, how does it differ from the previous one? What are the crucial intervention points for breaking the cycle of welfare and dependency? If persons have to be on welfare could they not be more effective as human beings, happier, better educated, even though on welfare? What have been the results of the vast rehabilitation programs undertaken in the United States? Given the deprivation and odds against them, what factor or factors contribute to some persons "making it"? How do lower-economic-status persons deal with stress? What factors strengthen their coping responses? These are only samples of the many questions that have to be asked. Presently, human welfare programs, from one point of view, are succeeding beautifully if the recipients cause no trouble and do not raise too much of a fuss. From this view, an ideal welfare recipient is one that does not hassle the welfare worker. A program that fosters competence, independence, and promotes psychological growth is bound to cause

trouble to the existing power structure. Powerlessness means safety for some. The phrase "power to the people" may be better understood in this context.

Consumerism and Community Psychology

In the delivery of most human services, the opinions of consumers have hardly ever been sought or, if given, are usually ignored. Until recently this held for almost the entire spectrum of human services including higher education. Massive programs have been launched with little or any pretesting, and usually without the funding of mechanisms for feedback designed to improve the systems. Medicare paid attention to organized medicine and how physicians felt about the plans for the program, but not to the recipients of medical aid. The physicians and the hospitals had the "clout." The consumers were getting the service and they should be grateful for it and should not presumptuously question the wisdom of the professionals. An effective community psychology "listens" to the recipients of services, not necessarily following their dictates but carefully weighing the inputs they receive. The disassociation of consumers from the delivery system and sometimes even from the setting of services results in a polarization that interferes with a mutuality of respect between provider and consumer. There is no sharing of problems, and there is therefore increasing ignorance of the stresses upon providers and consumers. Worst of all, the consumer takes no responsibility for his part of the transaction. Here again we have the question of developing a productive dialogue between those who have and those who have not. The fostering of responsibility is admittedly difficult, especially after years of procedures calculated to discourage the exercise of initiative.

As a competent community develops, it must allow for failures. Given the lack of experience and opportunity for leadership, it is perfectly understandable that many indigenous local leadership projects have failed and that the input of consumers has not necessarily been as helpful as had been supposed. This does not mean to say that attempts at local leadership and fostering of increased consumer participation should be abandoned. It does mean that the efforts have to be reevaluated, the reasons for the failures examined, and the project go back to the "drawing boards," so to speak.

When a giant space systems corporation with years of experience expends a half-billion dollars in

planning and production, and underestimates its costs by a hundred million dollars while all the while producing a super plane plagued with bugs and frequent crashes, the company is not criticized or penalized. On the contrary, efforts are made to help it recoup its losses. The defense of the United States is endangered. The complexities of communities and of the human beings in them are at least equal to those of the wonder plane and the interaction of the engineers, the production line, the space age materials and apparatus. The reasons for failing to return to the drawing boards in the case of social pathology experiments are of course many, perhaps the main ones being the failure to build appropriate corrective mechanisms into the system and the absence of sustained championing of the program and its goals. The citizens concerned do not have the sophistication, and in many cases they have not even been consulted, so they are not ego involved. There is of course much scapegoating couched in terms such as "it's impossible to do things in this neighborhood" or "these people don't give a damn." The leaders of the emergent competent community must go back to the drawing boards again and again. They cannot look for quick laurels and victories. Community psychologists, and indeed behavioral scientists generally, must be intimately involved in evaluation and feedback in most if not all community endeavors. They must expect failure and should not be ashamed of it. The processes by which success or failure comes about should be their concern.

Dangers of Involving the Consumers

The feedback from consumers is frequently highly critical, or, even worse, the consumers may begin to take involvement seriously. Some years ago the Office of Economic Opportunity (OEO) adopted the phrase *maximum feasible participation*, urging the poor to participate as much as possible in OEO-supported activities such as day care, Head Start, neighborhood information centers, family planning, and community development. Speaking as a former chairman of a board of directors of a community action program, I can testify that maximum feasible participation can lead to "outrageous" demands by consumers. They demanded evening hours for the city council, a neighborhood branch of the Welfare Department that would be open on Sundays, a substation for the county hospital, Saturday hours for conferences with teachers in the public schools, neighborhood-based policemen, a stop to rent goug-

ing, action against street violence, better bus services to work, more day care facilities, rodent and insect eradication, better fire safety in public housing, the dismissal of the Director of the Surplus Commodities Program, evening hours for the Employment Commission, plus better job counseling and opportunities for employment. The priorities were closely related to the more immediate needs of the consumers. The satisfaction of shorter range goals leads the community to believe that it has some input into the system, and longer range goals can then be worked for. The chairman has to learn some new rules of procedure. Roberts Rules of Order do not hold up very well. Most of the participants have never heard of them. The community has to learn to participate. Persons who have never had a chance to "say their piece" want to be heard. Meetings last far into the night. The distinctions between the Board of Directors at the table and the surrounding audience break down frequently. The observer of traditional meetings would most likely be appalled by the seeming chaos; yet things do get done. Having tasted a bit of success, the group wants more. They ask difficult questions. It is small wonder that the term *maximum feasible participation* was not stressed quite so strongly in the last few years of OEO. Communities that begin to see a little daylight start generating enthusiasm. Hope is terribly contagious. In some instances, community action programs have been taken over by so-called target groups with very sensible changes introduced. In others there have been disastrous polarizations. Communities, as they begin to develop in sophistication, will predictably begin to ask questions of professionals, even about professionalism itself.

One of the criteria of a competent community is the change in which power is transmitted to once powerless citizenry. The emergence of the sophisticated consumer should be welcomed, even though it may threaten the status quo. Parenthetically this emergence is not limited to the economically deprived alone. Sophisticated graduate students sometimes give us fits. Their demands for participation in graduate education are "unreasonable." Although obviously they have it far better than we had it in graduate school, they are still dissatisfied, they are presumptuous, their questioning of what constitutes a good program is premature since they have not had enough experience, their evaluations of instructors are not fair, their demands for relevance are in violation of our academic orientation, and their attempts at sharing in departmental gov-

ernment are a clear bid for power. Their demands really do not differ too much from other consumers in less sheltered settings.

Some Realities in the Development of the Competent Community

If the poor were articulate, knew their way around the system, and had time to spend building up resources, then they most likely would not be poor and lacking in power. What we take for granted is sometimes quite difficult. Luncheons and weekend retreats are not easily set up in impoverished communities. Communication may be difficult and people who work for hourly wages have to pay a relatively high financial price for taking time off. Appearing before the city council, the hospital board, or the school system can be a frightening experience, and the threat of punitive action on the part of employers is not to be taken lightly. In the complicated arena of striving for human betterment, a strategy might be to engage the efforts of a prominent, hard-working, ambitious member of the middle class. He could very well be the most appropriate person to help a less affluent and influential community. The notion is admittedly speculative and might lead to opposition on the part of social planners. Those who are interested in developing the competent community, however, might recognize that advocacy comes in many forms. Educated persons, after all, with many resources, hire lawyers to represent them in legal matters.

Although there have been many attacks on social benefit programs, the so-called War on Poverty has resulted in some increased competence on the part of communities. It is the type of competence that is only now beginning to emerge. Imagine, if you will, a group of Chicano parents asking for a meeting with the school principal to discuss plans for the coming year. They have had rather good experiences with Head Start or day care programs; they have participated in various ways. They have taken responsibilities; they have a feeling of just a little power and a little more hope that their children may get a better break in school. The principal is unsympathetic and outraged. How dare these "Messcans" even ask about the curriculum! He has told them it is the same for all first graders in the public school system (nondiscrimination is one of the ways of keeping the system as it is). The parents have had contact with persons who are interested in the situation. The parents

obtain expert advice about the discriminatory effects of intelligence testing, grade placement, and the like, from various sources including the community psychologist who was available to them in Head Start days. A million dollar suit is threatened against the principal, the teachers, the superintendent, and the school board, seeking exemplary damages as well as remediation of the current situation. The case is expertly worked up by a high-powered conservative lawyer, socially prominent, with political ambitions. He uses consultants skilled in community action and cognizant of the deleterious effects of inferior education on children. The complaint stresses the lack of validity of standard intelligence tests, the physical inadequacies of the school building, the lack of experience of the teachers compared to a school in a better part of town, the absence of a Spanish-speaking secretary, and the rudimentary bilingual program, etc. The school board capitulates in a hurry. Genuine changes are instituted. Parents are involved in planning a new school. Loud rumbles are heard about outside interference and agitators. Rather than gloat in the victory, community psychology should prepare for the predictable next step in which this same group of parents will go on to activities that will enhance their hopes and their power. In displaying this independence they may appear to be ungrateful to the community psychologist and others who were helpful to them. The rewards in community psychology are the growth of the community, not the thanks that are received from the beneficiaries.

It has been easier to keep groups dependent and therefore lacking in competence. The increase in competence of communities will result in many challenges and could be enormously rewarding areas for research. If programs are successful, individuals

and groups will assert their independence and do more things on their own, not doing it "our way" but "their way," different as it may be from ours. Achieving the goal of independence does not guarantee similarity of actions and attitude between initiators and those who presumably have benefited. On a poetic if not prophetic note, it is fitting to close with a reference to Tennyson's *Morte D'Arthur*, in which the dying king says, "I perish by this people that I made." Community psychology, in fostering the competent community, need not perish. It can grow and become more competent itself.

Corporal Punishment

ADAH MAURER *Committee to End Violence Against the Next Generation, Berkeley, California*¹

Fear of punishment has always been the great weapon of the teacher
The subject is so familiar that nothing more need be said about it.

William James, 1892

Part 1: The Semantics of Punishment

The word "punishment" comes from the same root (*L. poena*) as do the words "penalty" and "pain." Thus, we may assume that semantically the relationship is of ancient origin. "Cruel and unusual punishment" in the Bill of Rights was intended to prohibit torture for the purpose of extracting confessions or in retribution for unlawful acts. Both penalty and pain are implied. Webster's Dictionary lists a number of metaphorical uses of the word such as the deliberate punishment of automobile tires to test their endurance and safety; but as applied to human interactions, punishment means "to impose a penalty for some fault," "to inflict a penalty in retribution," or "to deal with harshly."

The synonyms "chastise," "discipline," and "correct" are differentiated by noting that while punishment indicates some retribution inflicted after a disobedience, chastise is likely to suggest the infliction of pain in the hope of effecting a reformation; discipline may involve punishment but always suggests action in the interest of order, rule, or control by authority; while correct may indicate a guiding away from error. There is much overlap and loose usage especially in the vernacular of those involved in the training of children, but the dual concepts of penalty and pain—or shame, deprivation, suffering, or loss—predominate.

When punishment is prefaced by "corporal" (*L. corpus*—body), the meaning is unmistakably that

of pain upon the body of the person, usually by some instrument such as a whip or paddle wielded by an agent of the offended jurisdiction. For example, "Corporal punishment was abolished in the Navy in 1850." In California juvenile institutions where corporal punishment is forbidden, restraint is permitted, but not the use of a strait jacket, gag, or thumbscrew or by tricing up, stomping, arm twisting, washing of mouth with soap, ducking, rabbit punches, curtailment of food, or extremes of temperature. Comparable forbidden school punishments would include, besides paddling, such refinements as stuffing the mouth with paper tissue, masking tape as a gag, shaking, ear pulling, lifting by the hair, or throwing against the wall or floor. Not definable as corporal punishment are fines, discharge, loss of privileges, and, in school, detentions, exclusions, and extra assignments.

Electric shock is a comparatively new method of inflicting pain and cannot thus be included easily and incontrovertibly. In varying degrees of intensity, it is designated as a punishing agent by experimental psychologists; it has been used to execute criminals; it is touted as a curative of depressive psychoses; and it is accepted with equanimity by telephone installers, for example, as a minor job-related annoyance. Even though it is painful and is applied to the body, electric shock can be called corporal punishment only when the intent of the punisher is taken into consideration. Clearly, the effort to pin down a definition of punishment, and especially corporal punishment, is not without its controversial aspects.

In scientific endeavors it is common for new words to be invented or for old ones to be given new meanings to fit the needs of the new tech-

niques. In computer technology, for example, common English words like "bit," "word," "address," and "loop" have special meanings within that particular discipline in addition to their ordinary meanings. Thus, when experimental psychologists define punishment as "a reduction of the future probability of a specific response as a result of the immediate delivery of a stimulus for the response [Johnson, 1972, p. 1034]," they are within the scholastic tradition which permits the use of any combination of phonemes to convey any concept, provided only that the terms are defined and that the new definition gains wide acceptance. The special definition of punishment as a technical term in experimental psychology is thus acceptable by these criteria.

The words "stimulus" and "response" used in so redefining punishment have not themselves been as carefully redefined from the common meanings. Stripping them of the ordinary implication of chronological sequence—stimulus first followed by a response—and assigning instead meanings tied to the status of the participants in which the experimenter (high status) gives the stimulus and the subject (low status) gives the response, regardless of timing, has gained wide but by no means universal acceptance even among experimental psychologists. Uneasy jokes about rats laughing among themselves at how cleverly they have conditioned the white-coated human to provide food indicate an awareness that the power relationship is an essential ingredient in the stimulus-response experiments and in the reasoning that follows from them.

Special technical definitions are useful within a discipline and among scholars who agree on the unexpressed emotive load of the terms that is conveyed without having either to state it or defend it. Communication is expedited by the sense of exactness these special terms convey, and further exploration of statistical parameters can be carried on free of the doubts and hesitations that more philosophical or semantically oriented phrases inevitably pose. The laboratory term "punishment" is stripped of all historical associations, all derivational implications. No consideration of the intention of the experimenter or of the feelings of the subject is admissible. The idea of retribution, the law of the talon, the eye-for-an-eye prescription, all are outside of and irrelevant to the pursuit of the scientific study of punishment. Aversiveness is only implied, not stated. "Any stimulus that reduces the frequency of the behavior that precedes

it [Baer, 1971, p. 34]," as the simplified version has it, does not limit in any way what the stimulus might be and does not require that it be painful or even unpleasant. The only stated criterion is that it be successful in diminishing or eliminating the behavior chosen by the experimenter as the object of the procedure.

Outside of the special environment of the laboratory or seminars in experimental techniques, the stripped-down-clean meaning of punishment as defined by experimental technicians shivers naked in a world in which tradition, ethics, social policy, law, legislation, child rearing, delinquency, war, feuds, power, gambling, daredevilry, ambivalence, masochism, and assorted evils and goods vie with the spirit of scientific inquiry for priority. Words used in a technical sense in the laboratory are heard elsewhere as if embedded in another matrix. In the case of computers, if laymen conjure up visions of loops and bits dangling like tinsel monkey wrenches inside a magic machine, no particular harm is done. But in the case of punishment, the consequences of a dual vocabulary can be fraught with legal, medical, social, and educational booby traps that range far beyond the narrow applications found in the literature on punishment in the laboratory sense.

A startling example of this is supplied by B. F. Skinner (personal communication, 1972). He wrote: "My name was being cited by both sides in a lawsuit in a southern city in which a school was being sued for using corporal punishment." Editorialized the *Phi Delta Kappan*: "Dallas public schools can keep the spanking rules they adopted after consultation with B. F. Skinner, the U.S. Supreme Court ruled recently [Editorial, 1973]."

In the city of Dallas, 24,035 instances of corporal punishment were recorded for the 1971-1972 school year, some of them so severe as to need medical attention and, in several cases, hospitalization. Thus, many thousands of children are subjected to punishment in the ordinary meaning of retribution and pain under laws that are defended, at least in part, by the laboratory definition of whatever will successfully change behavior. The dual definition is shockingly sharp in the cartoon by Johns in the *APA Monitor* (1972, 3[9 & 10], p. 3) of Scene: Rat Lab. Graduate student (with hair) to professor (bald): "Incidentally, we'll be short one rat this morning. The black and white one bit me and I bashed his skull in."

Psychologists seem to have been only peripherally aware that the laboratory definition has not been

adopted by the general public and that nonprofessionals do not understand the scientific attitude toward punishment with the same detachment that they do. In a personal communication (E. R. Church, 1963) we read:

Frankly, I had not considered the distinction between correction and retribution, although I can appreciate that it may be a distinction of importance for human adults and for children over a year. The writers of dictionaries have considerable trouble in making their definitions compatible with current usage and also internally consistent. Since the concept of punishment has been used by psychologists, at least from the time of Thorndike, without any implication of retribution, I think the dictionary will eventually recognize our usage.

To date, this has not happened.

This article examines in some detail the two sets of literature on punishment: the laboratory literature as analyzed by Johnston (*American Psychologist*, November 1972) and as reported in the *Psychological Abstracts* (Vol. 47, No. 1-6; Vol. 48, No. 1-4) contrasted with the field study literature listed in Bibliography 2. I attempt to show that the laboratory group has underemphasized the reality of educational and child-rearing customs while the field study investigators have underemphasized the scientific aspects of their efforts. This dual approach to the study of human activities has given rise to acrimonious misunderstandings. In the decade ahead, the legal and judicial aspects of students' rights and responsibilities are slated for a national airing. Psychologists, both laboratory and educational, will be called on to act as expert witnesses to testify for legislative committees and to lead community groups as they try to come to grips with the new concepts involved in the civil rights of children. It would be simpler if one set of psychologists raised the banner, PUNISHMENT WORKS! and the other set waved the placard, BEATING IS BRUTAL! Alas, our unexamined impulse to take sides in such a debate depends more on the history of our own infancy than on which school of psychology educated us. A careful analysis is thus overdue. I shall make a beginning.

The question is not whether or not psychology is a science. In the tradition of chemistry, laboratory experiments on behaving beings break up behavior into manageable bits, to quantify, manipulate, change, and control it. In the tradition of astronomy, field studies gather data by observation in search of patterns, relationships, regularities, and recurrences. Both sets of activities are scientific in that they attempt to discover true facts about

the objects of study and to bring order to otherwise miscellaneous phenomena. Both yield hypotheses that ultimately redirect human thinking and planning. In biology, both types of scientific activities have been used. Darwin on Galapagos and Mendel in his garden perhaps best exemplify the going out into the natural world to observe what is there as contrasted with manipulating bits within narrow confines to gain control over them. Darwin did not put the turtles through any set of tests, assigned them no tasks; astronomers cannot modify the behavior of the stars, but they are scientists nonetheless. To suggest that without manipulation, such as Mendel arranged in his pea rows, there is no science is patently absurd (Carlson, 1972, pp. 20-21). Psychology is indeed a science, and like biology it uses both observation in natural situations and testing in setups and reaches conclusions by both routes. As in all sciences where knowledge is thin and where conclusions contradict the folk traditions, informed hypotheses become best guesses. This is the position of psychology at the present time regarding corporal punishment of children in school.

In the 10 issues of *Psychological Abstracts* from January through October 1972, there are no entries under corporal punishment—nor have there ever been. It has never been a subject of sufficient concern to experimental psychologists to merit study except peripherally as one minor variable in studies of delinquency. Under "punishment" there are 108 entries, but 5 of these do not provide enough data to determine the nature of the material discussed. Of the remaining 103, 25 concern rats and 15 are about other animals such as monkeys, pigeons, turtles, and cockroaches, for a total of 40 animal punishment reports. Of the 63 studies concerned with human subjects, 20 used undergraduates, 19 used special adults (prisoners, alcoholics, stutterers), and 24 are about children. Of these 24, 5 were case studies ($N = 1$ or 2) in which electric shock was applied to severely retarded and severely disturbed children with successful reduction of unacceptable behavior reported. Four reports used loud sound or white noise as the punishment of choice; 2 used symbolic punishments, 1 used the word "wrong!" as punishment, and in 1 the punishment was to read anti-Semitic literature.

All of the above were studies built on the laboratory manipulation paradigm. Most were concerned with timing, intensity, manner of delivery, intermittent scheduling, or other technical niceties rather than the immediate or delayed effects on the subjects. The definition of punishment was in all

cases—though not always stated—whatever was convenient, measurable, and successful. A few of the studies merit individual review for the light they shed on our topic.

"The Effective Use of Punishment to Modify Behavior in the Classroom" (R. V. Hall et al., 1971) is one of the few studies in which the kind of punishing behavior is the subject matter. After noting the "controversy among the proponents of behavior modification regarding the use of punishment," Hall et al. conducted four experiments using as punishments: finger pointing with a shouted, "No!"; withdrawal of name slips; staying after school; and after-school tutoring. Their finding was that "systematic punishment procedures which do not result in strong emotional behavior do have a general applicability to classroom problems [p. 3]." Quoted out of context, the title and conclusion of this article could, and probably will be, quoted in defense of corporal punishment, with "strong emotional behavior" assumed by nonpsychologists on the school board to mean violent screaming, frothing, and thrashing about of the limbs. Consulting psychologists need to be prepared to counter such assumptions with a fuller report of this particular study pointing out that after-school tutoring is being labeled as punishment in spite of valiant efforts of educators to present it as opportunity. Otherwise, laymen may placidly assume that their prejudice in favor of old-fashioned whacks has been confirmed by modern psychology. This enhances their approval of "Psychology" but does nothing to increase their understanding of the effects of painful punishment on schoolchildren.

Similar misunderstanding has been caused by rapid readers of Donald Baer's (1971) article "Let's Take Another Look at Punishment" in *Psychology Today*. Both Hall et al. and Baer begin by defining punishment as "any consequence of behavior that reduces the future probability of that behavior [Hall et al., 1971, p. 1]" or "any stimulus that reduces the frequency of the behavior that precedes it [Baer, 1971, p. 34]." Both assume that corporal punishment went out with the gay nineties: "Hitting misbehaving students with rulers or making students sit in a corner with a dunce cap on their heads were common practices in the *early days* of American education [Hall et al., 1971, p. 2, italics added]."

I think that much of our revulsion regarding the use of punishment is based on a reaction against the truly inhumane conditions of *many years ago* that recur in literature—headmasters with canes, slave masters, prison turnkeys

with whips, bullies, orphanage overseers, snakepit mental hospitals. We like to think of such practices as long past, so when a therapist speaks objectively about the uses of punishment, we react as if he were asking us to forget all the years of progress and reform [Baer, 1971, p. 36, italics added].

There are many Americas. In the kindly America in which these experimentalists must have grown up, children were taught without blows to behave. The assumption that there have been "years of progress and reform" is one that many successful Americans make. Nat Hentoff, who researched corporal punishment for the American Civil Liberties Union, began his November 1971 (Civil Liberties) article with this admission:

If asked two years ago, I would have expressed doubt that corporal punishment was still an issue in our schools—except perhaps in a rural fastness or at the hands of a disruptive teacher who would be sternly warned by his principal not to beat a child again. Whatever the other failings of our schools, at least physical barbarism—and its festering psychic residue—were safely locked into the past. Or so I thought [p. 2].

"I was shocked out of my ignorance," he wrote as his research progressed. "Corporal punishment . . . is far from extinct. In a number of places, most egregiously Dallas, the brutalization of children appears to be a part of the core curriculum [p. 2]."

The documentation of the brutality there and elsewhere—slashings with tire chains, front teeth knocked out, strapping a 13-year-old on the testicles, dumping a boy head first into a garbage can and beating his buttocks while he struggled for breath, thrashing a girl so severely that her menstrual periods ceased for three months—school phobias of great severity have happened in California and Kansas, in Minnesota and New Mexico. Only 3 states, New Jersey, Massachusetts, and Maryland, forbid corporal punishment, and 17 states have passed laws expressly allowing physical punishment of pupils.

In the vocabulary of legislators, corporal punishment carries the dictionary and popular meaning: painful penalty as a consequence of the performance of a forbidden behavior. The behaviors so forbidden are defined by the teacher or principal of each school to suit his temperament and convenience. It may be anything from tripping a teacher to returning 30 seconds late after recess. Nor is it generally asserted that such paddling, punching, whipping, slapping, slamming against the wall, or other battering will "reduce the frequency of the

behavior that precedes it." The boy failed to say "Sir"; therefore, he has earned three blows.

In the vocabulary of the emotionally needy, primarily in the poverty culture, parents who have been identified as child batterers see punishment in the sense of pure retribution without consideration of future activities.

This group has a very strong sense of good and evil, right and wrong. These individuals have a very, very definite pattern—when an evil has been committed, punishment must occur. The punishment wipes out [the evil] . . . and so the parents feel they are really doing this child a special favor by inflicting this punishment, and this really makes them very good or right [Fawcett, 1972].

Documenting the difference between the laboratory and the lay meaning and emotive load of the word punishment does not suggest that one or the other is correct. My purpose is to reiterate the warning that the word carries markedly different meanings depending on the context and the user. Phrases associated with punishment and child-rearing practices when modified or used symbolically in the confines of the laboratory must also be translated for general applicability with as much exactness as is used in the experiments themselves. An example of such a related phrase that is wide open to misquoting and misunderstanding can be cited in the study entitled, "Interactions between the Facilitative and Inhibitory Effects of a Punishing Stimulus in the Control of Children's Hitting Behavior" (Katz, 1971).

"Hitting behavior" is one of the most persistent problems encountered by school disciplinarians. A study that purports to shed some light on how to keep boys from hitting others on the playground is likely to gain a wide audience among those who look to the science of psychology to solve a ubiquitous practical problem in playground control. The claim of experimental psychology to the status of a science lies in the assumption that behavior can be, and is, reduced to manageable bits and studied in a simplified, "pure" form under controlled conditions, quantified so exactly that mathematical comparisons have as much predictive value as do measurements of mass and energy of inanimate matter. To study hitting behavior in this way, one must determine first if it is indeed a homogeneous behavioral unit. In hitting the keys of a typewriter, in hitting a nail on the head, in connecting a bat with a pitched ball, in swatting a housefly, in probing for a solution, and in many other activities I may describe what I am doing as hitting behavior.

English is a rich, fulsome language, but it tends to make short words of Anglo-Saxon origin cover by analogy a wide range of meanings.

In the experiment referred to, the "hitting" of the title was directed at a toy clown that dispensed gumdrops or pennies and simultaneously or alternately an unpleasant sound. Subjects were given opportunity and approval for playing with the clown, and those who did not hit it for the dispensations were dropped from the study. The results of the study are not questioned; measurements were meticulous. But simulation "to avert many of the ethical problems associated with punishment operations" has its own special hazards. Striking a candy-dispensing inflated toy after this had been modeled by a male graduate student in a mobile unit situated on school grounds might by some stretching be considered a unit of behavior, but can it be equated with striking a peer who has emitted insulting remarks about one's mother, one's body build, or one's academic status? The element in common is the English word "hitting," a slippery concept at best, and the flexion and extension of some of the same muscles of the forearm. Such equating or extrapolating of results from one situation to the other is unjustified and dangerous. Nevertheless, the experimenter and his mentors in graduate school felt free to conclude that punishment, undiluted by subsequent or simultaneous reward, is more effective in extinguishing hitting behavior than is a combination thereof. He even went so far as to chide those parents who lavish affection on the punished child to reassure him of their continued love or to salve their own guilt at having struck a defenseless child or for some other subjective reason. The conclusion to be drawn in the applied situation in school that punishment for fighting on the playground should be "pure" and without incidental attentional or other compensations to facilitate reentry is an unfortunate non sequitur that cannot be justified scientifically or otherwise.

Among the impurities of units of behavior is the almost unstudied difference between prescriptive and proscriptive instructions. If rewards facilitate and punishments restrict behaviors, the way in which a behavior is described will determine which will be the stimulus of choice. Shall we punish a child for "hitting" or for not maintaining his cool? Shall we reward him for "not hitting" or for coming to report the provocation to the one in authority? Or to make it still more complex, shall we punish him for fighting or for tattling when these are the

only possible behaviors in a particular situation? How do children themselves see it? Do they consider any instance of punishment as the result of a sin of commission or one of omission? Or both? In a study of retrospective attitudes of adults concerning their own childhood (McKinney, 1971), it was found that they "consider the positive effects of their behavior to be the result of the right things they do, while they consider the negative effects to be the result both of the wrong things they do and the right things they fail to do [p. 78]." The well-known phenomenon that children rarely are able to remember or report what behavior or lack of performance preceded a particular punishment although the punishment itself is clearly imprinted on the memory may be a function of the mixed prescriptive or proscriptive description given to the child concerning his actions. "Results attributed to the relative efficiency of reward and punishment might take this differential into account [McKinney, 1971, p. 79]." It may be that "units of behavior" are a romantic fiction, unitary only semantically or in the verbal behavior of the experimenter and determined to need modifying or extinguishing without a certain analysis of alternatives.

"Out-of-seat behavior," an even more popular target for applied behavioral modification techniques in the classroom, demonstrates that the rigid rejection of so-called extraneous factors cannot be justified in the search for accuracy and effectiveness. Reward for remaining seated or penalty for standing up has been used to accomplish that most desirable of all conditions—to the teacher—that the child remain in his place rather than wandering about the room. But again, in-seat or out-of-seat is not a unit of behavior; it is necessarily imbedded in a situational matrix that is ignored at peril of ultimate failure.

Rising from a seated to a standing position is an act that is in itself neutral, neither good nor bad, dangerous nor safe, emotionally stable nor disturbed. It cannot possibly be eliminated from the repertoire of human activities without physically crippling the individual involved. In one situation, as when the bailiff so orders, it is legally required. In another, as when the national anthem is played, it is customary. In a third, as when dining with a group, it might be annoying. And in still another, as when the plane is taking off, it is prevented by a seat belt. In the classroom, it may partake of all of the above requirements at different times of the day.

The experimenter verbalizes that it is not im-

portant what the student "thinks" or "feels" but only what he observably does, but it is very doubtful if the student identifies his behavior as abstracted from the surround, or the rewards of tokens as other than a game that changes the emotional tone of the whole from "resentment of obedience requirements" to "enjoyment of chance possibilities." If the modifier refuses to admit this contamination of his clean "unit of behavior" manipulation, his lack of observation of the experimental field necessarily leads him to faulty conclusions.

The discovery that humans will perform allotted tasks for token rewards was made by the best minds of the Roman Empire and rediscovered post-feudally. The discovery that humans will concentrate on learning tasks for intrinsic rewards such as pleasure in good workmanship (Veblen) and joy in mastery and elation in discovery, the AHA! principle (Maslow), has yet to be considered by the manipulators. Small wonder that their successes are with the incompetent, the retarded, the disturbed, the young, and the powerless. No study to my knowledge has undertaken to discover the results of token rewards on gifted, creative people. Here, the results would be confused by the propensity to delay gratification, to sense both pleasure and pain in any reward, to feel embarrassment at fulsome praise and pleasure in being corrected because it signifies being taken seriously.²

A final critique of defining punishment as "any stimulus that reduced the frequency of the behavior that precedes it" must address itself to that word "any." We have been reassured that punishment does not have to be painful (Baer, 1971), nor necessarily result in a "strong emotional response" (Hall et al., 1971), but otherwise no limits have been placed on what it might be. This cavalier attitude about "any" contrasts with the paucity of punishing agents beyond electric shock and also with traditional deprivations used by schoolmasters since the profession was recognized in ancient Egypt. Let me suggest a few "punishments" that fit the approved definition but might not be so defined by the subjects. A hurt child's crying can be reduced with a kiss and a Band-Aid. An active child's jumping about can be reduced by placing

² Research regarding the effects of rewards on normal and gifted children undertaken since 1970 by Mark R. Lepper and David Greene of Stanford University suggests that a token economy with these groups interferes with, rather than facilitates, learning (Lepper & Greene, 1974, in press).

a television set 10 feet in front of him. The future probability of leaving the school grounds at noon can be reduced by providing free pizzas in the lunchroom. Pouting and "I won't" behavior has been eliminated by assigning an underplaced child to a higher and, therefore, compatible grade level.

The choice of "punishment" or, more properly, the "corrective," depends on the reason for the behavior. Out-of-seat behavior, in one school district during a period of 10 years, has been caused by a fistula involving the coccyx, a recent whipping on the buttocks, pinworms about the anus, tight underwear, no underwear, a minor kidney infection, an undiscovered visual defect, boredom, inappropriate subject matter seen as insulting (a story about white gloves at a girl's birthday party assigned to a Klamath River Indian boy), hunger, overtutoring, anxiety about a home situation (divorce, fire, brother arrested, illness of mother), a continuing feud, and a mental set caused by overhearing much criticism of the school as being "too permissive; they let the kids do anything they want to."

Choice of "punishment" thus becomes the major task of the behavior modifier. The casual adoption of candy or tokens as reward in all cases and the infliction of such aversive stimuli as electric shock, withdrawal of tokens, "time out" in various combinations, or other simplistic, narrow reductionism of "any" is not enough. Across-the-board one-menu-for-all methods are insulting and doomed eventually to passing as a ridiculous fad. The search for an individual prescription to fit a particular child in a particular situation with a particular background and history does not need to be seen as "Freudian," nor indeed as an abandonment of learning principles. It does require a more careful observation of the whole field and an individuation of recommendations for corrective measures. Without such case study methods, "psychology" has merely substituted electric shock for the whip, and corporal punishment remains the fate of the powerless. No plea for "objectivity" will still the moral revulsion of a free people against this return to barbarism.

The use of the word "corrective" is highly recommended in place of both reward and punishment as more accurate, as eliminating the semantic interchangeability of reward and punishment for prescribed and proscribed behaviors, as more likely to solve the dilemma of the ethical reservations of those who have learned to handle interpersonal exchanges without the use of force and fear, and, most important of all, to prevent the kind of mis-

quoting and misuse of learning principles that flowed between Harvard and the U.S. Supreme Court, thus affecting the cultural lag of Texas.

Part 2: Punishment Theory

Among psychologists, Adler (1970) was perhaps the first to set up community clinics and to offer general advice about child rearing. He strongly emphasized the futility of corporal punishment. "Corporal punishment in childhood," he wrote, "leads to low courage in adulthood." His followers have continued to emphasize natural consequences and to advise avoidance of power struggles with the young. "The punished student will want to avoid school, to look for means of escape, not means of meeting the difficulty [Ansbacher, 1956, p. 401]." "The punished shrug it off as the fortunes of war." And, "Our classrooms are filled with acts of retaliation [Dreikurs, 1957]." These conclusions, laced in the telling with many examples culled from teachers' stories, are open to accusations of lack of rigor. Control groups are noticeably absent; populations observed are not described as to intelligence, ethnicity, socioeconomic status, or other variables. Reported improvements on application of these prescriptions were not subjected to confirmation by objective tests. Nor is there much evidence that Adlerians listen to or observe the objects of their concern with any degree of scientific curiosity. Such

practical advice as they offer results in successful changes of behavior according to well-documented claims, but is, of course, vulnerable to accusations of "anecdotalism."

Freudian analyses of the effects on children of physical punishment might have followed from the essay *A Child Is Being Beaten*, except that the patient's confession was treated as fantasy and no more credence given its actuality than if it were dream stuff. The concentration on childhood sexuality has centered Freudian thought on the trauma of observing intercourse, the fear of castration, and the emotional impact of the family drama rather than on survival or other ego tasks. Neo-Freudians, however, have attended to these other aspects and have sought to fit them into the general framework of psychoanalytic thought:

The buttocks as the locus for the induction of pain (is considered) a safe locus. However, the anal region is also precisely the major erotic zone at the time at which the child is likely to be beaten there. Thus, it is aptly chosen to achieve deranged sexuality in adulthood [Bakan, 1971a, p. 113].

Trauma in childhood, including corporal punishment, may be associated with an interruption of normal sexual development and lead to numerous other forms of disorder [Alexander & Ross, 1961, p. 104].

Violent adults endured violence when they were young [Curtis, 1963, p. 386].

So widespread has Freudian thinking permeated the intellectual community that applications appear in the literature of other disciplines, notably anthropology. The cryptosexual aspects of paddling the anal area are described as a relic of primate behavior in *The Naked Ape* (Morris, 1967): "The female rump presentation posture as an appeasement gesture . . . with rhythmic whipping replacing the rhythmic pelvic thrusts of the dominant male [p. 137]." Not content with such a shocking accusation, he drives it home in specific detail: "It is doubtful whether schoolmasters would persist in this practice if they fully appreciated the fact that in reality they were performing an ancient primate form of ritual copulation with their pupils [p. 138]."

Credence is added to this analysis by an excerpt from a confession of a child beater:

There is no pleasure so pleasurable as the pleasure in another's pain. But one cannot get away with it completely. Somewhere a great deal of guilt follows on this sadism, and I am frequently burdened by remorse. I feel especially guilty that I sometimes get an erection and even have a climax during the beating. This is vile and hurts

me dreadfully [Recorded from an interview with a patient by E. J. Anthony, 1969].

Since the 1940s the largest amount of attention to the effects of physical hurt upon the educational process has been given by social psychologists (Bowlby & Burbin, 1950; Glueck & Glueck, 1940, 1950; Redl & Wattenberg, 1959; Redl & Wineman, 1962; Staub, 1962; Winder & Rau, 1962; Yates, 1962), by developmentalists (Bakan, 1971a, 1971b; Baldwin & Baldwin, 1970; Button, 1969, 1973; Eron, Walder, & Lefkowitz, 1970; Feshbach & Feshbach, 1973; Ilg & Ames, 1951; Kagan & Freeman, 1963; McCandless, 1967; McCord, McCord, & Howard, 1961; Munsinger, Sears, Maccoby, & Levin, 1957; Parke, 1970; Rutherford & Mussen, 1968; G. Watson, Douvan, & Adelson, 1966; Yarrow, Campbell, & Burton, 1968), by educational psychologists (Adams et al., 1971; Bernard, 1954, 1969; Bernhardt, 1964; Cutts & Mosely, 1941; Falk, 1941; Fish, 1970; Gnagey, 1968; Goodman, 1966; Gray, 1966; Haring & Phillips, 1962; Holt, 1967; Hymes, 1955; Kohlberg, 1963; Kounin, 1970; Kozel, 1967; Kvaraceus, 1945; Ladd, 1971a, 1971b, 1972a, 1972b; Larson & Karpas, 1955; Levy, 1969; Livarle & Seligson, 1970; Long, Morse, & Newman, 1965; Maurer, 1963, 1972a, 1972b, 1972-73, 1973; Morgan, 1938; Nash, 1963; Phillips, 1960; Richardson, 1969; Sheviakov & Redl, 1956; Spielberger, 1966; Tonningsen, 1972; Webster, 1968; Wolfe, 1953), and by members of other professions (Birmingham, 1971; Brooks, 1886; Grier & Cobbs, 1968; Hentoff, 1973; S. Holt, 1967; Illingworth, 1968; Kennedy, 1963; Morris, 1967; Radbill, 1968; Reitman, Follman, & Ladd, 1972; Vaigo, 1968; as well as the venerable Harriet Beecher Stowe, 1858). In addition to these writers are the behavior modifiers, carrot branch, whose findings in contrast to those of the stick branch emphasize the superior effectiveness of reinforcement schedules over those consisting of aversive stimuli (Bandura, 1969, 1973; Bandura & Walters, 1967; Buckley & Walker, 1972; Carter, 1972; Estes, 1944; Katz, 1971; Skinner, 1938, 1948; Solomon, 1964; Watson, 1924, etc.).

The verdict was unanimous: All were opposed. The flavor of these authors can best be absorbed by a small sample of culled quotations and short resumes:

Physical punishment was the favored disciplinary method of both fathers and mothers of delinquent boys [Glueck & Glueck, 1950].

Beating in child rearing actually has its roots in slavery [Grier & Cobbs, 1968, p. 138].

Corporal punishment escalates; discipline becomes harder to enforce. More energy is spent policing as children develop deviousness. The "bad boy" becomes the "hero"; gangs form to defeat the teacher (Bowly & Burbin, 1950).

Socially deviant behavior is common among boys subjected to restrictiveness and punitiveness (Winder & Rau, 1962).

Punishment may produce varieties of abnormal behavior such as rigidity, fixation, regression, aggression, displacement, primitivization, and resignation (Yates, 1962).

Among these studies are some that trace cruelty and punishment to its primitive origins: "Maltreatment of children has been justified for many centuries by the belief that severe physical punishment was necessary to maintain discipline, to transmit educational ideas, to please certain gods or to expel evil spirits [Radbill, 1968, p. 3]." From the schools of Sumer, 5,000 years ago, discipline oscillated between abandonment of the rod to its use to the point of savagery. We are entering a new phase of our history wherein one of our most serious concerns is the protection of our children (Radbill, 1968).

Basic texts, such as those by Falk (1941) and by Cutts and Mosely (1941), analyze the social structure and explicate the use of torture to maintain the power of one group over another. Both trace cruelty through the ages and conclude with reasoned, yet passionate, appeals for the abolition of corporal punishment in schools. These texts were published in 1941 during the height of World War II when the shock of the incredible cruelty of the Nazi concentration camps gripped the civilized world in a determination to eliminate official sadism for all time.

A more recent historical analysis of infanticide and child abuse was made in 1970 in which the phenomena were shown to be among the dominant themes in religious writings, in fairy tales, in Mother Goose rhymes, and in children's games (Bakan, 1971b). Current habits of spanking and slapping are seen as residual traces of the use of infanticide as a means of population control. During periods of famine, the numbers of children sacrificed to the gods increased markedly, thus providing symbolic relief but also "one less mouth to feed." During periods of comparative abundance or during wars or epidemics when the available food and the population reached an easier accord, the tendency toward substituting animals for humans softened the sacrificial rites. A related historical highlight

is the story of the Sephardim who instigated the addition of a rider onto the Naval appropriation bill as it struggled through Congress in 1950 banning the use of the cat-o'-nine-tails to scourge sailors (Birmingham, 1971).

Developmental studies of parent-child relationships are unanimous in their findings that punitive parents produce poorly adjusted children:

The child will do what the punitive parent demands only as long as he thinks that they will find out about his actions; he may not follow their prescriptions at all if he thinks he can "get away with it." The parent relying heavily upon punishment must continually be on guard, because his child is likely to rebel against his wishes [Berkowitz, 1964].

We anticipated that punishment for aggression would lead to inhibition of aggression. . . . Field studies contradict these predictions. . . . Increased aggression was routinely found to be associated with increased punishment for this behavior [Eron, Walder, Lefkowitz, 1970].

Other developmentalists spell out strong suggestions: Spanking episodes should be analyzed; parents are told: "Think over each situation to see where we missed the warning signs and how we could have acted differently [Ilg & Ames, 1951, p. 366]."

We must look carefully, thoroughly and rationally at the experiences of childhood and we must come out forcefully against those experiences that set the stage for later bigotry, brutality and violence—the symptoms of essential contempt for other people [Button, 1969, p. 121].

Among the educators we find the only apologists for corporal punishment (Bagley, 1923; Riebe, 1940; Stenhouse, 1967), but they tend to be quaint as well as dated. Most educators offer direction on how to avoid corporal punishment: "Regardless of state law . . . never touch a student in anger. *Never*. This means shoving, shaking, pinching, jerking at clothing, stepping on toes, and so on [Gray, 1966, p. 26]."

Exposé books describing in horrifying detail the happenings in junior high schools flooded the market in 1970 (Kozol, 1967; Levy, 1969; and many more). One of these books (Kozol, 1967) sparked the changing of the laws regarding children's rights in the state of Massachusetts; the other raised the specter of racism in describing the vicious methods of control, including karate chops, used in the classroom, and the counterculture of the children that this inspires and models. White teachers (in a black school) consciously treat with kid gloves all

those children whose parents are active (Levy, 1969).

Some educators address their attention to the effects on the individual child: "When we make children afraid, we stop learning dead in its tracks [Holt, 1967]." Some speak to teachers: "We need more discipline, not less, but self discipline [Hymes, 1949]."

"Punishment escalates when not controlled—even by men fundamentally well intentioned [Tonning-sen, 1972]."

Gentle coaxing of administrators to try nonpunitive techniques on "kids accustomed to restrictions, threats and punishments" (Ladd, 1972b) offers a helping hand into new ways to even the most hard-bitten.

Some educators point stonily to the evil efforts of the raw exercise of primitive power on the undefended and powerless. Studies indicate that vandalism is the youth's attempt at retaliation for punishments and humiliations suffered in school (Kvaraceus, 1945), and strong demands are made for protective legislation for children. "Beating of children which is really an assault upon them should be abolished by law. Those who defy the law should be treated as any other law breaker [Adams et al., 1971, p. 172]."

The father of American behaviorism opposed whipping and beating for his own reasons. They are not advised, he wrote, because they cannot be regulated according to any scientific dosage. Punishment is either too mild to establish a conditioned negative response, or too severe, thus stirring up unnecessarily the whole visceral system of the child. "It is either too rare to meet scientific conditions or too frequent thus making for habituation and masochism [Watson, 1924, p. 184]."

The next wave of behavior-oriented psychologists adopted both of these hands-off policies. "We are now discovering at an untold cost in human suffering . . . that in the long run punishment doesn't reduce the probability that an act will occur [Skinner, 1938]." And again, "It works to the disadvantage of both the punished and the punisher [Skinner, 1938]." That he has been misquoted has been documented earlier, but it should be reiterated that there were no buttons to trigger electric shocks nor any attachment that emitted noxious stimuli in the Skinner box.

Most learning theorists, however, have used electric shock to motivate an animal as casually as most people flip a switch to start a motor. Their attention has then been free to consider the permu-

tations of the experimental design. Rarely is the focus on the punishment itself. When it has been, as at the University of Pennsylvania, bewilderment seems to have been the chief result:

I have not specifically considered the age factor in discussing the effects of punishment. . . . The data are a bit cloudy and in some cases seem to show that early punishment builds up an immunity to punishment, while in other cases the data seem to show that early punishment sensitizes animals to future punishment. Obviously there are factors at play that we do not understand [R. L. Solomon, personal communication, 1963].

Somewhat more murky to those engaged in out-of-laboratory behavior is the summing up: "I have argued that the emotional effects of punishment are felt through the Pavlovian conditioning of reaction and that the instrumental effects of punishment are noted through the reinforcement of instrumental acts through punishment termination [R. L. Solomon, personal communication, 1963]."

The interrelationship between corporal punishment of humans and ethical standards is of course the moot point:

It is a complicated problem and the interrelationship between psychological efficiency and ethics seems evident. Clearly an inefficient use of punishment, one that has to be repeated over and over again, approaches depravity. The same punishment used once with excellent effects could be called wise kindness if the behavior that was discouraged by the punishment was of the type that could be harmful to the individual. We are in no position to make these ethical judgments because our psychological knowledge is so poor; however, someday our psychological knowledge will not be poor, and then ethical judgments must be made [R. L. Solomon, personal communication, 1963].

Since 1963 when the above was written, our psychological knowledge and our ethical judgments to be based thereon remain firmly embedded in ignorance. In pleading for a continued suspension of ethical judgments until we have had more time to experiment with punishment (Johnston, 1972), the experimentalists of this persuasion must begin to recognize that time has run out. Ethical judgments are being made. Furthermore, ethical judgments are changing rapidly from a willingness to live with primitive punitiveness to a recognition that permitting one child to be battered is to subject all of our children to the danger of victimization. When as an adult the erstwhile battered child shoots 18 people from a Texas tower, kills 14 nurses in a Chicago residence, or slays a movie colony party in Hollywood, the blood is on the hands of those who would give aid and comfort to the punishing parents who shaped these lives with-

out learning that corporal punishment is an ethical evil.

Children will soon become a comparatively scarce commodity because of the new freedom vouchsafed women to control their own reproductive processes and to bear only such children as they wish. Scarcity increases value. The winds of change are blowing toward greater valuing of fewer children. Under these conditions it behooves experimentalists to confront ethical judgments now, and social, developmental, and educational psychologists to subject their ethical judgments to the rigor of careful assessment.

Could we set aside our obsession with control? Could we, as the pediatricians have developed a symptomatology of the battered child, begin to develop a profile of the overpunished child?

Work in progress indicates a near perfect correlation between the amount and severity of physical punishment endured by a child from 2 to 12 and the amount and severity of antisocial aggressiveness that he displays during adolescence (Button, 1973; Welsh, 1974). But during the years that the beatings are a daily diet and before the child is strong enough to retaliate or defend himself, he is in school and we should be able to recognize and rescue him. Could hyperactivity be environmental rather than genetic? Could short attention span be a survival tactic developed by the child in a continuously punitive home? Are there glandular changes, such as an increase in adrenalin output that permanently changes the body chemistry in the young human under continual severe stress? Are there "soft signs" that point to overpunishment at least as clearly as signs point to neurological handicaps? What really is "minimal brain damage" and can these symptoms be induced by early brutality?

All of these have been advanced as possible correlates of severe and prolonged physical punishment. A first study of the "at risk" child sees him as one whose apparent brightness does not show up as more than a dull IQ. He is danger oriented, tense and guarded, visually hyperalert, lies blandly in defense of his parents, and seems precociously "mature" (Martin, 1972). Is this the whole picture? Here, again, control groups are needed, especially because many grown males will claim defensively that they were punished as children, suffered no ill effects, and certainly did not become criminal.

These unknowns, rather than schedules of reinforcement or even rehabilitation techniques, must

be unraveled before we can begin to see any hope that the next generation will be less traumatized and less violence prone than our own.

Current Status of Graduate Education in Psychology

PETER F. MERENDA *University of Rhode Island*¹

In anticipation of resolutions endorsed by the Vail Conference participants relative to psychological academic programs, in general, and the professional training of psychologists, in particular, and in recognition of the fact that there is considerable controversy within the psychological discipline itself regarding graduate curriculum content, educational objectives, and models of training, the study reported here was undertaken. Throughout its recent history, academic psychology has been confronted with great and continuing divergence of opinion with respect to the nature of graduate training programs, generally, and with specific reference to the appropriate education and training model for graduate students in the applied areas of psychology, notably clinical psychology. Note the many national conferences held on this theme: the Boulder Conference, the Chicago Conference, and now the Vail Conference.

Method

INSTRUMENT

A two-page questionnaire was developed to elicit, on a national scale, both factual information and some opinions from the chairs of departments of psychology. The questionnaire was mailed out at the end of July 1973 to 60 chairs of departments of psychology in universities in the United States offering doctoral-level programs in both basic and applied psychology. The great majority of these departments are offering APA-approved doctoral programs in applied psychology, principally clinical psychology. By the end of August 1973, a total of 48 (80%) schools had responded.

SAMPLE

The chairs of psychology departments who responded were from 32 state universities and 9 private universities. The majority of these schools maintain rather large doctoral programs in psychology. Of the 48 departments that responded, 35 reported having more than 30 doctoral students matriculating at any one time; only 10 reported having between 11 and 30 students; and only 3 schools reported having fewer than 10 students pursuing the doctorate at any one time. With regard to the number of doctoral degrees conferred annually, the sample is comprised of 35

departments reporting more than 10; 11 departments reporting between 6 and 10; and only 2 departments reporting fewer than 5.

Results

NATURE OF DOCTORAL DEGREE

All departments responding to the questionnaire offered the PhD degree in psychology. Only two schools reported offering an additional doctoral degree through the department of psychology. They were the University of Illinois (PsyD) and Teachers College, Columbia University (EdD). No other doctoral degrees were reported.

CORE COURSES

Of the 48 departments in the sample, 30 reported requiring the successful completion of core courses of all doctoral students in psychology. The number and nature of these courses and proseminars varied among the departments claiming to hold to this requirement. The distribution of the number of credit hours involved in the core course requirement is presented in Table 1. The median number of required credit hours was 17.50 (based on $n = 28$).

The nature of these required courses is presented in Table 2. The courses in this table are listed in descending order of frequency of report.

The data of Table 2 show clearly that the 30 departments that maintained a core of required courses for their doctoral students considered the following content areas in psychology to be most important: statistics (29), social psychology (12), child/development psychology (13), learning (11), personality (10), and physiological psychology (8). These data also reveal the diversity in requirements.

¹ A copy of the complete report, with supporting materials, may be obtained from the author.

Requests for reprints should be sent to Peter F. Merenda, Department of Psychology, University of Rhode Island, Kingston, Rhode Island 02881.

TABLE 1

Distribution of Credit Hours Reported for Core Courses

Credit hours	Frequency
42-46	1
38-41	0
34-37	1
29-33	1
25-28	5
21-24	3
17-20	3
13-16	4
9-12	5
5-8	3
<5	2
Variable	2
Total	30

A total of 32 separate courses were given by the 30 respondents. This level of diversity regarding the specific required core courses parallels the diversity reflected in Table 1, which reports the number of such courses required by each of the 30 departments. The typical requirement is approximately 6 courses, but the reported number of credits required ranged from 6 (2 courses) to 45 (15 courses).

The remaining 18 departments, which reported that they did not require doctoral students to take any specific core courses, offered a variety of reasons to explain why such courses were not demanded. These reasons may be broadly classified into the following categories: (a) Outside minor areas are substituted for core courses; (b) qualifying or special examinations are substituted; (c) the faculty simply could not agree as to what should constitute the core.

CONDUCT OF COMPREHENSIVE EXAMINATIONS

The 48 departments that responded to this survey reported the following categorical information regarding the committee that is responsible for the conduct of the PhD comprehensive examinations: student's program committee (19), departmental examining committee (19), special committees or other examining bodies (11). The 11 departments that reported examining procedures of the latter category submitted the following explanations of how these examinations are conducted:

1. Each student must pass an advanced, in-depth examination in his chosen area. This examination is graded by a committee of at least two faculty members. Ordinarily, a student must pass this test by the end of the second year.

2. Ad hoc committee conducts examinations depending on exact nature of student's specialization.

3. Performance on core courses constitutes preliminaries. Decisions are made at the end of the first year. Students also must prepare a publishable paper in a significant area.

4. Ad hoc committee conducts examinations depending on the student's goals.

5. Examinations are conducted by each area group, consisting of at least three staff members.

6. General comprehensives (departmental examining committee) and preliminaries (student's own program committee) are administered.

7. First-year exams are the responsibility of a committee, one half of which is comprised of departmental examining committee and one half by student's program committee.

Second-year exams are the responsibility of a student's program committee. As an alternative to taking a three-hour exam in major specialty, a three-hour exam in methodology, a two-hour exam in specialty area of student's choice, and another two-hour exam in a second specialty area outside the major, the student may negotiate a contract

TABLE 2

consisting of a series of accomplishments, subject to faculty approval.

8. A divisional examination is administered.

9. Written examinations are given, to which entire faculty contributes in writing questions, grading, and overall evaluation.

10. Graduate Record Examinations are given by the college.

11. The department examines the candidate in history and systems and in a second elective area of psychology. The program committee examines the student in his major area. The oral comprehensive examination involves departmental (on occasion) and nondepartmental representatives.

These data were further analyzed from another standpoint, taking into account whether core courses were required. This two-dimensional breakdown is presented in Table 3. The figures in parentheses are the proportions of the row totals represented by each of the cell frequencies. They serve as a better description of the situation, as reported by the 48 respondents, than do the cell frequencies themselves. Departments requiring core courses for all of their doctoral students reported that these same students take comprehensive examinations given by their own program committees or by other arrangements in greater proportion than those students who are not required to enroll in (and pass) required core courses. On the other hand, these latter students are examined by departmental examining committees or special examining committees in greater proportion than the former.

SCOPE OF COMPREHENSIVE EXAMINATIONS

Of the 48 departments that responded to the questionnaire, 26 claimed that the comprehensive examinations administered to their doctoral candi-

Not required	9	(50)	6	(33)	3	(17)	0	(0)	(18)
Total	18		19		4		7		48*

Note. Figures in parentheses are the proportions of the row totals represented by each of the cell frequencies.

* One department reported examinations by both department and program committees.

dates are broad and comprehensive in scope. Another 10 departments reported that the comprehensive examinations are, in part, broad and integrative and, in part, narrow and specific. Only 4 claimed that their comprehensive examinations were narrow and specific. The remaining 8 departments reported that the comprehensive examinations varied, essentially depending on the area involved.

DISCUSSION AND IMPLICATIONS OF FINDINGS

From the data obtained in this survey (see Table 4) it becomes immediately obvious that at the present time, the PhD degree is, for practical purposes, the only doctoral degree that is being awarded in psychology, in both the basic and applied areas. Taking into consideration the fact that the Vail Conference endorsed the doctor of psychology degree as the *appropriate* degree for the professional training of psychologists at the doctoral level (Korman, 1974), it becomes more obvious that the conference is asking all but one university (University of Illinois) to deliberate the changes.

Another resolution passed by the conferees at Vail is that the nature of core academic and professional training requirements be broadened. It was further recommended that "nonfunctional" requirements be modified or deleted. With the exception of statistics and to a lesser extent with the exception of social, developmental, learning, personality, and physiological psychology, there appear to be substantial discrepancies as to what should constitute a "core" among those departments that require a set of core courses of their doctoral candidates. The determination of how to modify and broaden—or whether or not to modify or broaden—the "core" is anticipated to be most complex and difficult.

Considering the varied reasons given by the minority departments as to why they have eliminated the core requirements, confusion must also be anticipated in establishing graduate program requirements so that "these requirements . . . [contribute to] the assurance that students acquire competence in the performance of professional activities [Korman, 1973, B-I-1]."

The Vail Conference evidently did not address itself directly to the issue of the nature and scope of comprehensive examinations required of doctoral students. Perhaps this was due to the fact that requirements are university-wide and are established and monitored by the graduate faculty at

large. However, on the basis of the data arising from the 48 departments that responded to the survey questionnaire, the following conclusions are tenable: (a) The examinations are, in the main, broad and integrative in scope; (b) the examinations are administered primarily by either departmental examining committees or the student's own program committee. In departments not requiring specific core courses of the students, the data show a greater tendency to examine students through a departmental examining committee rather than through the student's own program committee. In those departments requiring core courses, however, arrangements other than examination by either committee are possible, except for students in departments that do not require core courses.

In summary, the results of this survey reveal that at the moment doctoral training in psychology leads, for all practical purposes, to the PhD de-

gree; that the majority of departments offering advanced graduate work in psychology insist on a core of required courses that is quite variable; and that the comprehensive examinations taken by these students are, in the main, broad and integrative and more likely to be administered by either a departmental examining committee or the student's own program committee. Finally, for those departments in which a core of courses is not required of all doctoral students, there are, nevertheless, substitute requirements, for example, demonstration of competencies and knowledge in content areas through examinations, or the successful completion of a minor academic area.

Membership Characteristics of the Division of School Psychology of the American Psychological Association

BARTELL W. CARDON *University of Pennsylvania*¹

One of the specialties within psychology that has been receiving increasing attention is school psychology. Within the American Psychological Association, the Division of School Psychology (Division 16) has steadily gained in membership, activity, and influence. At the time this article was written (summer 1973), Division 16 was fifth in total membership among the divisions and second only to Division 12 (Clinical) in number of representatives in Council.

Despite its size and visibility, there seems to be relatively little awareness among members of APA as to the composition and characteristics of the Division. Indeed, it would appear that many members of the Division harbor misperceptions.

Size and Geographical Distribution

As of June 1973, the Division of School Psychology had 2,485 members (127 Fellows, 1,346 Members, 1,012 Associates). Table 1 provides a geographical breakdown of Division members by zip code area.

Academic Degrees

The distribution of Division membership by degree is found in Table 2. Approximately 49% of its membership have earned the doctorate and 51% hold the master's or bachelor's degree. Of those

holding the doctorate (1,213), 70% have PhDs. Although complete information is not available, it can be said with confidence that the large majority of members holding the master's degree (1,260) either received the degree after completion of two or more years of graduate study or have completed at least one year of study beyond the master's or both. Likewise, it can be stated with confidence that the majority of members holding the bachelor's degree (12) have completed one or more years of advanced study.

The dramatic increase of members earning the doctorate during the 1961-1970 period (Table 3) very likely represents the cumulative effects of the creation of formal school psychology programs during and slightly preceding the 1961-1970 period. More than 75% of all currently existing programs originated after 1955 (Cardon & French, 1968-1969). The first doctoral graduates of those programs would have received degrees in 1958-1960, with the number increasing thereafter.

Approximately half as many students in school psychology are prepared at the doctoral level as at the master's and intermediate levels (Cardon & French, 1968-1969). Of Division members obtaining their highest degree since 1961, more hold the doctorate than do not. It may be inferred that the Division is more attractive to school psychologists who hold the doctorate than it is to those who do not.

Primary Employment

For purposes of this study, employment is defined in terms of university versus nonuniversity settings. Approximately 75% of members of the Division are employed principally by an employer in a non-university setting (Table 1). They work in public and private schools and clinics, for test publishers, and so forth.

¹ The author was, at the writing of this article, Secretary of Division 16 and a Representative to Council. All information has been taken from membership records of the Division, the *American Psychological Association 1972 Membership Register*, and a short questionnaire sent to approximately 150 members for whom adequate information was not available. Appreciation is expressed to Judy Stephenson who compiled much of the data.

Requests for reprints should be sent to Bartell W. Cardon, Graduate School of Education, University of Pennsylvania, Philadelphia, Pennsylvania 19174.

TABLE 1

Division 16 Membership by Geographical Location and Type of Employment: 1973

Zip code area ^a	Nonuniversity		University		Total	
	N	%	N	%	N	%
00	20	1.1	16	2.2	36	1.4
0	274	14.9	56	8.9	332	13.3
1	459	24.8	146	23.1	605	24.3
2	139	7.4	49	7.7	187	7.5
3	85	4.6	54	8.5	139	5.6
4	201	10.8	83	13.1	284	11.4
5	138	7.4	41	6.5	179	7.2
6	169	9.1	54	8.5	223	9.0
7	74	4.0	40	6.3	114	4.6
8	66	3.6	28	4.4	94	3.8
9	227	12.2	65	10.3	292	11.7
Total	1,853		632		2,485	

^a 00 = foreign;

0 = Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, Vermont, Rhode Island;

1 = New York, Pennsylvania, Delaware;

2 = Maryland, North Carolina, South Carolina, Virginia, West Virginia, Washington, D.C.;

3 = Alabama, Florida, Georgia, Mississippi, Tennessee;

4 = Indiana, Kentucky, Michigan, Ohio;

5 = Iowa, Minnesota, Montana, North Dakota, South Dakota, Wisconsin;

6 = Illinois, Kansas, Missouri, Nebraska;

7 = Arkansas, Louisiana, Oklahoma, Texas;

8 = Arizona, Colorado, Idaho, New Mexico, Nevada, Utah, Wyoming;

9 = Alaska, California, Hawaii, Washington, Oregon.

The distribution picture is interesting. Those areas with the fewest members have lower practitioner (nonuniversity)-academic (university) ratios than do areas with more affiliated school psychologists. That is, proportionally more members living in areas with few affiliated school psychologists are associated with universities than in areas with many affiliated school psychologists. The highest proportions (approximately 35:65) of university school psychologists are found in Areas 3, 7, and 8 (see Table 1). These areas represent a band extending across from Florida, west to Arizona, and north through the Rocky Mountain region. The lowest proportions (approximately 20:80) are found in the northeastern and far western states.

Sex

The current interest in and concern for the professional status of women recommends an in-depth evaluation of sex status within the Division of School Psychology, as reflected in membership. Some data reflecting sex have already been presented.

TABLE 2

Division Membership by Highest Degree and Sex: 1973

Degree	Males		Females		Total	
	N	%	N	%	N	%
PhD	607	39.6	239	25.0	846	34.0
EdD	283	18.5	84	8.8	367	14.8
Master's	633	41.3	627	65.7	1,260	50.7
Bachelor's	8	.5	4	.4	12	.5
Total	1,531		954		2,485	

There are 954 women (38.14% of the membership) in the Division (see Table 2), 323 (33.18%) of whom hold the doctorate. Slightly over 61% (1,531) of the membership is male, with 58.1% holding the doctorate. Although half (49.6%) of the Division members not holding the doctorate are female, only one in four (26.6%) of the doctoral members is female.

A look at Table 3 is informative. Female members with the doctorate are consistently outnumbered by female members not holding the doctorate when compared across years of last degree. Males with the doctorate outnumber those without at all years of degree except the 1941-1950 period. The influence of World War II may be seen in these data.

Of the males, 68.2% (1,046) are employed in nonuniversity settings. They represent 56.4% of the total nonuniversity school psychologists within the Division. Of the females, 84.6% (807) are employed in nonuniversity settings.

TABLE 3

Division 16 Membership by Sex and Degree: 1973

Year	Male			Female		
	Doc-torate	Nondoc-torate	Total	Doc-torate	Nondoc-torate	Total
1971	28	15	43 ^a	9	0	9 ^a
1961-1970	543	346	889	187	252	439
1951-1960	244	199	443	72	162	234

1931-1940	22	11	33	13	65	78
1921-1930	9	9	18	1	16	24
1911-1920	2	0	2	1	1	2
1901-1910	0	0	0	0	0	0
Total	890	641	1,531	323	631	954

^a Applicants obtaining degrees in 1971 were generally not yet eligible for Division membership at the time of this study.

There are 632 Division members whose primary employment is university related, 148 (23.4%) of whom are women. The female-male ratio of university school psychologists varies greatly across the nation. Women are best represented in Area 0 (28.6% versus 71.4%), Area 7 (27.5% versus 85.4%), and Area 3 (14.8% versus 85.2%).

Of the female members, 47.8% (456) are Associates, 48.1% (459) are Members, and 4.1% (39) are Fellows. Of the male members, 36.3% (556) are Associates, 57.9% (887) are Members, and 5.7% (88) are Fellows. Although a larger proportion of the total male membership holds the status of Fellow than the females, it is noteworthy

that a larger proportion of female members holding the doctorate are Fellows (12.1%) than males (9.9%).

It would be difficult to judge if there is a difference by sex in level of Division activity. One cannot overlook, however, an interesting fact. Although women represent less than 40% of Division membership, they presently hold more than half of the seats on the Executive Committee.

REFERENCE

- Cardon, B. W., & French, J. L. Organization and content of graduate programs in school psychology. *Journal of School Psychology*, 1968-1969, 7, 28-32.

Erratum

In the Report of the Executive Officer: 1973, in the June issue, there are two errors. On page 368, the second sentence of the paragraph headed Publications should read: "In 1973 the journals contained 15,000 text pages, each of which had been carefully redacted for accuracy and format by one of the Association's 14 journal technical editors." The other 3 technical editors are employed on other publications of the Association, not the journals. On page 374, the second sentence of the paragraph headed Manpower Resources should read: "In 1973 the 46,000 questionnaire records received from the 1972 Survey were processed and converted into a computerized data file."

Audited Financial Statements
of the
American Psychological Association
for the
Year Ended December 31, 1973

It has not been the practice in the past to publish to the membership the audited financial statements for a given year immediately after their availability. Rather, the financial reports have been incorporated into the Treasurer's annual report. The cycle of events being what it is, the Treasurer makes his report at the annual business meeting of the Council of Representatives. By the time the Treasurer's report is then published to the membership, many months have elapsed.

Accordingly, and with the Treasurer's consent and approval, we are publishing the audited financial statements for 1973 independent of the Treasurer's annual report and will plan to follow this practice annually hereafter. The chief advantage is that the information will be made available to members of the Association as soon as possible. These re-

ports will normally be published without interpretive comments. Such interpretation will be reserved for the Treasurer's annual report when a critical analysis is made of past experience, current operations, and future prospects.

Having said the above, it nevertheless seems appropriate at least to invite members' attention to the fact that APA sustained a deficit of \$72,940 in 1973 which followed a \$120,338 deficit in 1972. These figures can be seen in the accompanying "Statement of Operations and Net Worth." Not seen is the fact that these deficits in 1972 and 1973 followed a \$21,987 deficit in 1971—making three consecutive years of deficits. Clearly, deficits cannot be allowed to continue, and the matter of stabilizing APA finances is receiving the close attention of the governance structure.

Board of Directors
American Psychological Association, Inc.
Washington, D. C.

We have examined the financial statements of the American Psychological Association, Inc., for the years ended December 31, 1973 and 1972. Our examinations were made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances.

In our opinion, the accompanying balance sheet and statements of operations and net worth and changes in financial position present fairly the financial position of the American Psychological Association, Inc., at December 31, 1973 and 1972, and the results of its operations and changes in financial position for the years then ended, in conformity with generally accepted accounting principles applied on a consistent basis.

Ernest A. Ernest

NOTES TO FINANCIAL STATEMENTS

AMERICAN PSYCHOLOGICAL ASSOCIATION,
INC.

December 31, 1973

Note A—SUMMARY OF SIGNIFICANT ACCOUNTING POLICIES

The Association is a tax-exempt organization dedicated to the advancement of psychology as a science and as a means of promoting social welfare.

Method of Accounting

The records of the Association are maintained on the accrual basis of accounting. Consequently revenue is recorded when earned and expenses as incurred.

Grants

The Association receives grant funding from federal agencies and private foundations, with amounts received restricted for use in fulfilling the terms of the grants. Revenue is recognized only to the extent of Association expenditures under the grants. Overexpenditures are borne by the Association and unexpended funds are returned to the grantors.

Property and Equipment

The National Headquarters building and furniture and fixtures are carried on the balance sheet at cost and are being depreciated on a straight-line basis over the useful lives of the assets as follows:

National Headquarters building, initial cost	40 years
Building additions	10 years
Furniture, fixtures, and equipment	10 years

Divisions

The Association has 33 autonomous divisions of special psychological interest which members may elect to join. As a service to the divisions, the Association will, upon request, act as collection agent for assess-

ments paid by division members (\$199,000 in 1973). The accompanying financial statements exclude the accounts of these autonomous divisions.

Note B—NOTE RECEIVABLE FROM OFFICER

The note receivable from officer bears interest at 6½%, is secured by a deed of trust, and is payable in equal monthly installments, including interest, through 1999. The note is callable at the Association's option upon 90 days' written notice. The Association has given notice to call the note due and payable as of April 18, 1974.

Note C—MORTGAGE NOTE PAYABLE

The mortgage note is payable to a bank, bears interest at 5½%, and is secured by the land and building occupied by the Association. Quarterly installments, including interest, are \$50,770 payable through 1990.

Note D—RETIREMENT PLAN

The Association has a pension plan through which it makes contributions on behalf of eligible employees for the purchase of annuities. Contributions under the plan were approximately \$86,000 in 1973 and \$76,000 in 1972.

Note E—COMMITMENTS

During the year the Association entered into a 5-year lease for data processing equipment for the period January 1, 1974, to December 31, 1978. Minimum annual lease commitments are approximately \$102,000 for the years 1974 through 1978. The lease is cancelable during the term of the lease upon 90 days' notice with retroactive price adjustments.

Rental expenses incurred during 1973 and 1972 were as follows:

	1973	1972
Data processing equipment	\$74,729	\$35,287
Office equipment	16,979	11,506
Other	5,963	2,074
	<u>\$97,671</u>	<u>\$48,867</u>

A Real Dilemma

Regarding Nolan's (March 1974) article, I agree that *ought* does not follow effortlessly from *is*, and that Skinner may have his head in the sand by encouraging scientifically minded psychologists, all nice fellows, to set up a perfect culture. But are we not also being proverbial ostriches if we reject science when questions of value arise? There is a real dilemma here. If values are not bestowed by supernatural forces, they must develop from within the natural system in biological and, particularly, cultural evolution (e.g., Campbell, 1972). The latter includes complex, social signaling processes known as *rational discussion*, for example, scientific interchange. There is no assurance that *any* of the paths we follow, such as those blazed with the help of science, will be healthy for us in the long run, yet we find ourselves pursuing science. On what basis do we decide to stop when questions of value arise?

What Is Psychology About?

D. O. Hebb's (February 1974) article was unfortunately another example of dichotomous thinking that continues to fragment *people* into fictional parts under the guise of defining "psychology." In his attempt to espouse "scientific" fictions over

a variety of other "nonscientific" fictions, Hebb made several unscientific conclusions:

Science is the servant of humanism, not part of it. Combining the two ruins both [p. 74].

Mind then is the capacity for thought, and thought is the integrative activity of the brain . . . [p. 75].

Free will thus has a physiological basis, in the relative autonomy of the activity of the cerebrum [p. 75].

No scientific evidence was given for these conclusions in the article or in the Sperry (1968) article that he touted so highly.

Now I do not wish to argue for any of the so-called nonscientific approaches that Hebb used as straw men to demolish; nor do I wish to argue against Hebb's scientific position. My concern, however, is with this kind of either-or thinking—the "I'm right, they're wrong" attitude in psychology. I am very much involved in this issue of "what psychology is about" both as a teacher in the newly opened Psychological Studies Institute in Palo Alto, California, and as a practicing psychotherapist. An alternative to the "I'm right, they're wrong" attitude has been presented in my book, *The Nightmare of Success*. Psychologists are just as prone to get trapped in the "success syndrome" as are the business executives and professionals described in the book.

Being very "right" in one's position can effectively prevent one from being "wrong," in other words, different from what *has been* successful. Hebb mentioned both Claude Bernard's dictum that "those who have an excessive faith in their own ideas are not well fitted to make discoveries," as well as Barber's (1961) article, "Resistance by Scientists to Scientific Discovery." But Hebb apparently forgot their admonitions

in his "right" answer to "what psychology is about."

Both Hebb's comment about "surprises" (not "rightness") being found "in the truly creative act," and Carl Rogers' comment about "serendipity" in the act of making discoveries, reported in Rogers' article (February 1974), could serve as an introduction to the approach that I presented in my book as an alternative to being right. In fact, I call the process by which highly successful and right individuals become real and human again "serendipity psychotherapy." Like Hebb, I heartily recommend it to those who wish to form opinions on this issue, and even to those who do not.

-Fem-ale or -Male Authorship?

Immediately after reading "The History of Psychology Revisited: Or, Up with Our Foremothers" (Bernstein-[fem] & Russo[fem], February 1974), which decried the inability of readers to determine whether a reference is authored by a male or a female, I read in the same issue of the *American Psychologist* "What

Psychology Is About" (Hebb[mal], February 1974). The latter article mentioned the early Russian psychologist Shenger-Krestovnikova, of whom I have never heard. I am nevertheless sure that this psychologist was female because the Russian language distinguishes between male and female last-name endings. This suggests a much-needed repair to our method of citation. We should add, at the end of each name, a suffix to indicate sex. The suffixes that immediately come to mind are *-ma*, for male, and *-fe*, for female. But perhaps my male chauvinism is showing, for the female suffix is quite similar to the Yiddish expletive for dirt. Alternatively, we could use *-mal* and *-fem*, although the male suffix would suffer from "bad" connotations. The second set of suffixes seems preferable, and I urge their adoption.

Comment on Rogers

I was surprised to hear Carl Rogers (February 1974) say that I have "cheated the profession" by refusing "to permit the nine-hour confrontation we held at the University of Minnesota to be released." As I remember, it was not my permission but my advice that was asked for, and I said that the quality of the recording was so wretched that I did not feel it fair to offer the tapes for rental or sale. I have no objection whatsoever to the tapes being made available if anyone is willing to listen to them. I have heard a recording made by a member of the audience which is much clearer and might be a better candidate for release.

I do not, however, relish the prospect of editing my share of a nine-hour transcription, and I should not want a transcription circulated without editing, particularly considering the bad recording. That was certainly never part of our original agreement.

Some Ambiguities in the Escape from the Ambiguous

This note is a comment on Sheehan's (November 1973) article. This comment is divided into two parts: The first part is based on what would ostensibly appear to be a reasonable interpretation of Sheehan's account; the second part is based on a consideration of the experimental techniques employed by both Barber (1969) and Sheehan. Predominantly, our concern is with Sheehan's critique of what he called the operational paradigm or model. His critique was essentially an analysis of Barber's (1969) experimental procedure. Sheehan maintained that Barber's model contains an artifact; we maintain that the term *artifact* was used too loosely by Sheehan. Artifact refers to a specific kind of error, and, although it was evident that Sheehan had legitimately found a fault in Barber, this fault is of a different nature.

First, artifact arises typically in the following situation: An experiment is conducted in which there is an experimental group and a control group. These groups by definition differ only with respect to the presence of the experimental factor in the experimental group. All other factors in the two groups are supposed to be the same. If experimentation demonstrates a difference on the dependent variable between the two groups, the difference is

attributed to the experimental factor. If it turns out that the experimenter, in exemplifying (Campbell, 1969, p. 358) the experimental factor, unwittingly introduced some aberrant or unspecified independent variable such that the difference in the dependent variable can be shown to be produced by this ignored factor, we say that the original result was *artificial*. Thus, experimenter bias, or *demand characteristics*, or the *Hawthorne effect* are elements unintentionally introduced into experimental situations and have subsequently been shown responsible for differences in dependent variables.

Heuristically, one might view Barber's recent studies (for a summary, see Barber, 1969) as purporting to expose an artifact. Barber pointed out that results that appeared to be due to hypnotic trance were *artificial*. Among the factors prerequisite to the production of a trance, one finds something called *task motivation*. In numerous experiments, Barber presumed to show that when task motivation was added to the control condition, the superiority of the hypnotized subjects disappeared.

Orne's real-simulating model discussed by Sheehan (1973) is a typical example of a situation in which artifact arises. Although both Sheehan and Orne referred to the simulators as "quasi-controls," this seems an unnecessary qualification once it is made clear that the quasi-control is really the experimental group. What makes the situation look different is that Orne wanted to show a *faking* instruction to be an inhibiting factor so that the "experimental" simulators would do "worse." The simulators were treated in every way like the hypnosis subjects except for the additional instruction to fake. The instructions to fake can be regarded as the experimental factor. Furthermore, the artifact, the so-called simulation effect (Sheehan, 1973, p. 984), was found to be an element unwittingly introduced with the instruction to fake, again fulfilling the desideratum for normal artifact situations.

The objection raised by Sheehan against Barber, however, was not of the typical kind. Task motivation may be visualized as the control condition, and standard hypnotic induction as the experimental condition (containing both task motivational and hypnosis variables). Seen in this fashion, Sheehan was not trying to show that the experimental factor contained some other unwittingly introduced variable; rather, he attempted to show that the control condition possessed something that the experimental situation lacked, namely, more social pressure or constraint. In order to grasp the importance of the distinction between the Sheehan-type artifact and the usual artifact, it is necessary to examine the fundamental purpose of the control group. When doing an experiment, why have a control group? Why not have just an experimental condition? The answer is that the purpose of the experiment is to determine whether a hypothesized relationship exists between one factor and another. It is not always possible, and frequently not even meaningful, to isolate this factor. Other factors may also be present, yet by the introduction of a control group the experimenter seeks to decrease the likelihood that these factors are influential in producing the result. Whatever factors are common to both experimental and control groups are thought to be eliminable in accounting for the differences obtained between these groups. Sheehan contended that the control group does not necessarily serve this function because the control factors may play different roles when the experimental factor is absent than they do when it is present.

Sheehan's position struck at the very heart of the use of control groups. Specifically in the case of Barber, the objection was that task motivation introduces, or at least increases, a variable of constraint when presented without the rest of the induction. If this objection is valid in the Barber case, then it is a potential objection to all studies involving experimental and control groups.

Indeed Sheehan's claim was logically valid and potentially applicable to the numerous studies that employ control groups. Sheehan's objection was tantamount to saying that a given factor may have a particular effect in one context and a different effect in another context. In other words, an experimental factor may interact with a factor in the control condition, and such a possibility is certainly real.

The fact that such interactions are possible does not mean that every experiment employing a control group contains a Sheehan-type artifact. On the other hand, because so many of the variables in experiments are unspecified—situational, instructional, subject—the possibility of such an artifact in a control group looms large. Of course, the burden of uncovering such interactions lies with the one who proposes such an interaction, and the question arises of how such an interaction can be demonstrated.

To understand how an interaction may be demonstrated empirically, it is necessary to discover what factors are presumed to be interacting. In the general analysis of the control group that we are proposing, a Sheehan-type artifact assumes that an experimental factor is interacting with some factor in the control situation. But as we have already indicated, task motivation, because it is represented as lacking something that standard induction does not, is in reality the control group for the experimental condition (i.e., standard hypnotic induction). Sheehan did not seem to recognize this as the true empirical problem that he posed, but it seems clear that the politics behind his efforts were to save the non-task-motivating part of the induction from Barber's experimental onslaught.

Accordingly, the proper experiment seems to be one that will show an interaction between the non-task-motivating parts of the induction and the task-motivating portion. Such an experiment would include four conditions: (a) the usual "control" (i.e., no special instructions, just the suggestibility tasks), (b) task motiva-

tion alone, (c) non-task-motivating instructions alone (suggestions of drowsiness, etc.), and (d) instructions of both kinds, that is, the "standard hypnotic induction." This is a familiar factorial design, and the results of an analysis of variance should make clear whether a Sheehan-type artifact is present.

The actual experiment that Sheehan performed (Sheehan & Dolby, 1974) was quite different from the one outlined above. Why is this? The answer within the framework presented here is that Sheehan skipped a step. What do experimenters do when they discover an interaction? They attempt to explain it, to postulate a mechanism that would account for it. This is what Sheehan did. He assumed that the interaction existed and endeavored to explain it as acting through the variable of "social constraint." The interaction occurred *because* the non-motivating parts of the induction inhibited the constraint created by the task-motivating instructions in the control condition. This was what Sheehan sought to show.

Second, the analysis to this point is logically coherent and makes important and valid methodological points. It is based on the assumption, however, that in the Barber procedure there is some one thing, called task motivation, present in both the experimental (standard hypnotic) and the control (task-motivating) conditions. As Barber (1969, p. 71) observed, standard induction consists of (a) hypnotic variables (the subjects being told that they are to be hypnotized and then given suggestions to relax, become drowsy, and go to sleep) and (b) task motivational variables (cooperate-try statements and statements that it is easy to respond to suggestions and to experience the suggested effects). One might have conceived of the experimental situation as consisting of actual pieces of magnetic tape presented to each set of subjects. The piece of tape that contained the task-motivating instructions (b, above) would be played to both groups; another piece that contained the rest of

the induction procedure (*a*, above) would be played only to the experimental subjects. Neither Barber (1969) nor Sheehan (Sheehan & Dolby, 1974)¹ followed such a procedure. The task-motivating instructions are presumed to be interwoven into the standard hypnotic induction; however, there was a blatant incongruity between the wording of the instructions given to the task motivational subjects and to the standard induction subjects.

This materially alters the situation. The obvious differences in what is meant by *task motivation* in the two conditions violates a rule of methodological procedure and therefore makes it impossible to apply the analysis discussed in the first part of this comment. The rule is that except for the experimental factor, the control and experimental groups should be treated in as like a manner as possible. This was not done, and there appears to be no reason for this failure. Since Sheehan's instructions followed those of Barber (1969) verbatim, the responsibility for this gross neglect seems to be the latter's.

The burden to show comparability between the two groups should be Barber's. The claim that the differences in what we call *task motivation* in the two groups make no difference because there is no difference in the dependent variable (suggestibility scores) begs the question and is therefore clearly invalid. At the most fundamental level a vast difference exists between experimental and con-

trol groups; hence one should be fully justified in concluding with Sheehan (1973) that "task motivational subjects could be responding because of their condition and hypnotic subjects because of their condition, both involving different reasons [p. 987]." At any rate, it seems to have fallen Sheehan's lot to show empirically that the obvious differences in Barber's two groups do make a difference in suggestibility scores. Sheehan provided us with a variable of constraint in terms of which these two sets of instructions differ, but calling this operation *artifact finding* is erroneous. To call every error an artifact would be misleading.

By assuming the burden of proof, Sheehan put himself on the defensive. His actual empirical work seemed less convincing than a preexperimental examination of the instructions given each group. In submitting the three sets of instructions (those which comprise task motivation, standard hypnotic induction, and modified hypnotic induction) to the same set of raters to assess the dimension of constraint, he also created an occasion for the introduction of artifact. Asking the same raters to rate these similar instructions carries a demand or expectation that differences exist. A more rigorous technique would be to employ independent randomly selected groups to respond to each set of instructions rather than have one group rate all three. Also, his actual results with the three sets of instructions showed no difference in the dependent variable. To get significance he had to use the "change scores." There seems to be little precedent for this and, as

Sheehan himself admitted, it is an *ad hoc* procedure. Furthermore, this "change score" confounds difficulty and order.

Finally, it should be pointed out that the concept "social constraint" is very vague. Task motivation is similarly vague. If one explores the differences between these two concepts, it is difficult to distinguish them clearly. Indeed, is there a way to define task motivation so that it does not imply some social pressure or constraint? What if subjects were asked simply to rate the sets of instructions for their degree of task motivation instead of social constraint? Would the ratings have been different? Perhaps Sheehan emphasized that the two sets of instructions are not identical in task motivational and hypnotic settings, but, as we argued, one has every reason to expect this from the obvious differences in their wording.

Psychology in Action

THE APA MINORITY CONSULTATION PROGRAM

FRED STRASSBURGER *American Psychological Association*¹

Over the past several years, the American Psychological Association's Committee on Equality of Opportunity in Psychology (CEOP) has been interested in and concerned with the numbers of minority students entering and remaining in the field of psychology. The desire to do something concrete in this area led to the development of Project Impact. Through a program of consultations with graduate departments of psychology, this proposal was designed to help establish models for the recruitment, training, and practice of psychology among minority group members.

A memo from CEOP, summarizing ideas for a grant proposal designed to increase the representation and meaningful participation of minority group members in the profession of psychology, was submitted to the Board of Directors in May 1971. The Board approved the plan in principle and authorized continued development of a grant proposal. Project Impact was eventually put into its final form by an ad hoc committee that met on January 15-16, 1973; this group consisted of Carl Eisdorfer, James Jackson, Glendora Patterson, and Jacquelyne Jackson, the Chair of CEOP.

While Project Impact was being debated and developed, the Board of Directors at its September 1972 meeting had the idea of starting something like a miniature pilot project along similar lines within the already ongoing activities of APA. The minutes of that meeting say: "Because the Board felt that work in this area should not be delayed until outside funds are available, it directed that consultation on minority affairs should be a focus of the 1972-1973 APA consultation program with the hope that experience from early consultations can be used in strengthening the proposal." Actually, some members of CEOP were inclined to reject this pilot project on the basis that it might be seen as a substitute for Project Impact and would thereby reduce the pressure to seek funding for Project Impact. There was also a feeling that a project like this, on such a

small scale, was bound to fail and that negative implications for Project Impact would be drawn from such a failure. Finally, however, CEOP decided to take advantage of this opportunity, after establishing that the two projects were really independent and that work on Project Impact was not contingent on the success or failure of the minority consultation program. The purpose of this report is to present some results of the consultation program.

A certain amount of funds allotted to the Visiting Scientist Program was set aside to initiate a Minority Consultation Program. At this point, a letter from the APA Executive Officer was sent to about 300 colleges and universities calling attention to this special focus and asking for the institutions' expression of interest in having minority affairs consultants visit their campuses. Thirteen schools did express a positive interest in the program; two schools sent letters saying they would be willing to supply consultants to such a program. Letters of interest varied considerably, from the obviously lukewarm to the enthusiastic and insightful.

It might be noted that, although only 13 of 300 responded to the offer of a minority consultant visit, some of the psychology departments responding were at very large institutions, and a few would probably be classed as belonging in the upper ranks of psychology departments; however, the so-called "top 10" were not among the respondents.

The Ad hoc Committee on the Visiting Scientist Program, at the suggestion of the Education and Training Board, decided it would be able to fund the visits (two visitors per school) to all the institutions requesting them. The members of CEOP met and drew up a list of consultants who were geographically near to the requesting institutions and who seemed appropriate to the particular needs, expressed or perceived, of the institution. Letters were sent and calls were made to the selected consultants, who expressed a surprising 90% interest in working with this project, despite the fact that they would receive no stipend for doing so, except for room and board, and transportation. After the consultants had agreed to serve, the institutions were notified and further arrangements were worked out between the institutions and the consultants.

¹ The author would like to thank Dorothy Thomas for her help in preparing this report.

Requests for reprints should be sent to Fred Strassburger, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

At the time of this writing, eight visits had been completed and evaluative reports had been received from all eight of the institutions and ten of the consultants. A reading of these reports reveals that at least four of the institutional reports could be rated clearly as "positive," while three might be classified as "mixed"; none is clearly "negative." Of the consultants' reports, seven are clearly "positive," two could probably best be described as "mixed," while one could definitely be called "negative."

More instructive, however, than these figures, and more interesting, are some actual quotations from these reports. The following remarks were selected to point out consistencies that appeared to emerge from the reports.

In answer to the question, "Indicate what you regard as the major, special problems in dealing with minorities the host institution faces," the visitors' report of a well-known southern university stated:

It appeared obvious that _____ has difficulties in understanding the particular needs of its minority students to combine traditional psychological training with more relevant pursuits. Second, because minority students are new to _____, communication is a definite issue. Third, the lack of minority (including women) faculty appears to be a drawback in allowing for nonacademic supportive relationships between faculty and minority students. Fourth, and perhaps most persuasive, is the traditional nature of the department. Unlike other large traditional programs that are flexible, due to their size, the smallness of the department maintains certain norms, values, etc., which appear to be threatened by the desire for certain different types of training by minority students. This is a problem shared by departments across the country and it is in no way peculiar to _____.

Other comments from this report included:

A disadvantage from the black students' point of view is the small percentage of black students in other departments and in the undergraduate college with whom to form a mutual support base. The typical student is seen as either indifferent or unresponsive to black students. The student body is seen as primarily either ultraconservative or apathetic, politically. Greekdom is still very big there (it is 1950s in the North). All students interviewed are single, which no doubt enhances their feelings of isolation.

The students, by and large, feel that the faculty views them as less than adequate students. There was doubt expressed as to whether they would in fact graduate. The stereotype under which they perceive themselves to be laboring was actually reflected in some interviews with faculty members. This stereotype had to do with black students thinking more concretely, having more than the average difficulty with writing and statistical skills.

They [the students] feel that the Department is a bastion of white males with prejudice toward both females and blacks. They expressed a need for black and female faculty. The female students tend to address the faculty person by title, and the male students tend to use first names in addressing faculty members.

The proximity of black colleges was pointed out to them. Their response was to the effect of feeling that they are discouraged from working with persons at other institutions.

From the same report, the following are observations about the faculty:

The faculty extended as warm a welcome to the visiting consultants as did the students.

The faculty . . . were genuinely interested in the problems of recruiting and retaining black students and were readily available to us for interviews or providing information.

There were parallels and contradictions between the faculty's perceptions of the black students and the perceptions attributed to them by the students themselves. . . . The terms *deficiencies* and *remediation* arose spontaneously in every interview with faculty members. There seemed to be among the faculty almost a "set" for remediation that may be in the nature of a "self-fulfilling prophecy."

A striking difference in perception was noted in treatment of black students. The students felt there were some discriminatory practices on the part of some of the faculty, although this was not cited as of major significance. In contrast, the faculty seemed to feel that black students were given above-average or "special" treatment. One faculty member described the assignments of the black students as "more plush" (allowing for more free time than the average graduate student had), to make up deficiencies.

One faculty member stressed an important factor, that not enough feedback was given to the students nor was it given to the entering black student early enough. Some faculty, it was felt, were hypersensitive in their responses to black students. Interestingly, the faculty member that came across, to this observer, as being the most comfortable in discussing the black students, both their strengths and weaknesses, was the faculty member most admired by the black students.

The institution involved in this case also submitted an evaluation of the visit, of which the following comment is a brief sample:

Not only the consultants' advice but also the internal dialogue stimulated by the conferences should be most helpful. The consultants approached the task in a very probing, frank discussion of the department's problems relevant to minority group members. It seems most likely that these conferences will have a constructive effect on future departmental actions. The consultants' role in setting the stage for this probable development cannot be overestimated.

Although positive responses such as the foregoing were more typical, it is of interest to quote from the one clearly negative visitor's report. This visit was to a small eastern college. She described the program as follows:

The consultation consisted of an invitation to make a presentation of our own ideas to the faculty. . . . There was no opportunity to talk with other campus community members. . . . The advice offered consisted of the following . . . [here followed a list of "imperatives" offered to the faculty].

This consultant, in response to a question on whether a consultation program could be helpful in aiding the host institution resolve its special problems, replied "Consultation on a regular basis could help if with group work; however, it must be requested by the institution and still would have low probability of per-

ceivable success." Additional comments made by this consultant are as follows:

There was poor communication of the purpose of the visit between APA, the institution, and the consultants. This must be cleared up. . . . The visit should be with smaller groups of concerned persons at a time and others beside faculty should be available. . . . At this point, I would not like to be considered as a visitor unless the program is reorganized to be more effective.

Of obvious interest here is the report written by the institution about this particular visit. Following are relevant comments:

Due to poor communication, only one conference was held at which our staff of 36 faculty were present. Only one member of our staff is black and one third are women. . . . Advice was offered to the faculty primarily in the area of community psychology regarding power sources. . . . Although some hostility was engendered in the beginning, in the final analysis the thought-provoking ideas came through.

In response to the question, "What is your single, most important problem related to minority students?" this department's representative answered, "Motivating some black students to attend classes and keep appointments." To the question, "Could such a program aid you in the future?" he responded, "Perhaps, but I am not sure how because we have a viable college affirmative action committee that has been established this year on a college-wide basis." Regarding suggestions for improvement he commented, "Keeping lines of communication open through responding to phone calls and letters is important. Because of problems in this area we eliminated other uses to which the consultants might have been put if scheduling did not have to occur at the end of the semester."

Perhaps it should not be surprising, but it is certainly instructive to note how much overlap there seems to be in problems perceived by and around minority students at the campuses visited. One typical report, made by a visitor to a university in the Rocky Mountain region, stated:

The university offers a very attractive program that is of potential benefit to Chicano and black students. Their emphasis on school guidance and school psychology appears very desirable to the minority students I have had the opportunity to speak to. The department has a minority affairs committee which impressed me as being conscious of its responsibilities and, as a result of this committee, has approved a curriculum change adding a number of black and Chicano culture courses which they strongly recommend to their students. . . . Nevertheless, despite attractive professional training programs, the addition of minority culture courses, and the willingness of the faculty to take some steps toward improving minority education, extremely serious problems exist with regard to minority student affairs:

1. The percentage of minority students is extremely small, despite attractive course offerings.
2. Financial support levels at the university, for students of any race or color are pitiful. . . .

3. The faculty currently has one black and one Chinese on appointment as instructor or higher. This creates problems of relating among students who feel that the Anglo instructors do not adapt their teaching or understanding of human behavior to specific minority concerns when these are appropriate. The relative lack of role models on the faculty was unanimously decried by the black and Chicano minority students I spoke with.

4. The administration from the highest authority down, is perceived by blacks and Chicanos as not committed to improvement of minority student relations. The perception here is that money exists at the higher levels for supporting minority education programs but the administration persistently blocks these attempts at releasing funds.

5. The administration's failure to meet with me in conjunction with clear evidence of large financial expenditures for construction landscaping etc. does possibly call into question their priorities for financial allocations.

6. The faculty teaching load is nothing short of lack-breaking. A faculty member's commitment to improvement of the plight of minorities can at present only come at the expense of his or her family or other free time.

One last bone of contention between students and administration concerns admission standards. Again, students complained of "institutional racism" in the department's depending on the GRE (Graduate Record Examination) scores for admission. I discussed with faculty our department's brief experience with GRE scores and minority students, in which it appears that a minimal GRE verbal score was associated with success in our program. We also discussed alternatives (e.g., tutorials, special tracks) for the minorities. We arrived at no real solution to this problem, other than an agreement that standards of high professional quality must be met in professional programs regardless of standards used in admitting students.

This consultant made some recommendations to APA on how to improve the minority consultants program. One recommendation was that APA should catalog resources available to departments eager to improve their minority student programs. APA perhaps could funnel information through the minority consultants about federal state and private agencies that might fund programs aimed to assist in the recruitment and retention of minority students. Another recommendation was that APA might better train its consultants to obtain important information from the university authorities in a position to support or withhold support from minority programs. This particular consultant favored specific action on target areas such as financial aid for minority students rather than attempts to change attitudes; this feeling was by no means universal in the reports.

It seems fairly evident that some programs are more able than others to benefit from a project such as this and that some types of consultants have more to offer than others. Some programs appear more able to admit shortcomings and lacks without becoming overly defensive about them. At the same time some consultants while able to confront the issues directly and honestly, do not go to a program with their minds made up that whatever they find will be bad and that there can be no convincing evidence of good and sincere intentions.

The more receptive programs made a great deal of time available to the consultants, but did not necessarily feel the need to plan each minute that the consultants were on campus. They did see that a maximum number of students, faculty, and administrators were available to the consultants. Receptive consultants recognized the realistic difficulties in scheduling these various groups in a one- or two-day period and bent over backward to adapt their own schedules to suit. They were also more likely to want to engage in open give-and-take discussions as opposed to giving lectures, advice, or prepared formulas. It appears to me that the consultants who expressed no concern about the lack of fees are likely to do a better job; likewise, receptive departments are more likely to come up with the funds to pay for the visits.

The reports give the impression that the greatest benefit that may come from a visit is when it acts as a catalyst for a campus dialogue that continues after the consultants leave, or it reopens a dialogue that, for various reasons, had died before the consultants arrived. A closed-minded consultant is not likely to start such a dialogue, nor is one who is terribly uncomfortable with an unstructured give-and-take situation or who is too unaggressive to ask to see the relevant people

on campus. A more interesting question is whether departments that ask for minority consultants, but with a clear lack of enthusiasm, can still benefit from the visits. Not surprisingly, one gets the impression that the most positively perceived visits are to departments that looked forward eagerly to them and did a good amount of advance preparation.

Nevertheless, it appears that some of the departments that had initial reluctance about the program still expressed positive feelings about the results of the visits, as did the consultants who made the visits. Indeed, in discussions within CEOP about the potential of Project Impact, it was generally acknowledged that programs which felt under some duress to "volunteer" for the program might in the long run benefit the most. Timely support to the factions within a campus that created the request in the first place could conceivably have a positive long-range impact. It is true, however, that where reluctance exists, it is incumbent upon the consultants to do as much of the advance preparation as feasible. In any case, the results of the minority consultants program, judging from the reports submitted, would indicate that there is a real need for an expanded program of this type, such as is envisaged in Project Impact.

Decide for yourself!

Audition this new cassette-and-text Course for ten days—you decide whether or not it can improve your interviewing skills!

Today—more than ever—it's important to hire the right people for the right jobs. This dynamic new Course shows you how to make a patterned, in-depth evaluation of an applicant during an interview—pick people with skills, drive, and motivation. In just a few short hours, you can master the techniques of the **evaluation interview**—the results-oriented system that turns up an amazing amount of information from applicants. So much information, in fact, that you can predict with ever-increasing accuracy just how well applicants will perform if hired . . . how soon, if ever, they will be ready for promotion . . . even how far they are likely to move up in your organization!

McGRAW-HILL'S COURSE IN EFFECTIVE INTERVIEWING

Study guide . . . 320-page course manual . . . a fascinating 90-minute learning experience on audio tape . . . interview guide and interview rating form

From helping an applicant to talk spontaneously through every phase of guiding, controlling, and interpreting an interview, Kenneth A. Fear's **THE EVALUATION INTERVIEW** (2nd Edition) shows you exactly how to handle personnel interviews. Accompanying this hardcover manual are two audio cassettes (approximately 90 minutes) that feature "actual" interviews, including an interviewer, interviewee, and guide (or "voice over"). Performed by professional actors, these interviews give you a real feeling for what to do—and what *not* to do—to get the information you need to help you decide whether or not you've found the right person. Also included are a study guide, an interview guide to help you cover all critical points, and an interview rating form to sum up your findings.

10 DAYS' FREE EXAMINATION

McGRAW-HILL BOOK COMPANY

1221 Avenue of the Americas, New York, N.Y. 10020

Send me the complete McGRAW-HILL'S COURSE IN EFFECTIVE INTERVIEWING (079484-7) to examine for 10 days. At the end of that time, I will remit \$29.95 plus tax, postage, and handling costs, or return Course postpaid. (Remit in full with this coupon, plus any tax, and McGraw-Hill pays all postage and handling costs.)

Brain Control

Fact or fantasy

There are serious proposals to alter human behavior on a large scale through brain stimulation and psychosurgery.

Dr. Valenstein incisively separates awesome science fiction from equally awesome science fact. He provides the historical perspective and experimental evidence necessary for your understanding-in-depth of the field.

For example...

Can we control violence by altering the brain?

What are the implications of brain operations on hyperactive children?

Will "pleasure centers" in the brain constitute the future opiate of the people?

What are the ethics of brain operations?

"A book of great social importance"—*Science*

"Wise, scholarly and written with grace and clarity."—Jerome Kagan, *Harvard*

BRAIN CONTROL: A Critical Examination of Brain Stimulation and Psychosurgery, by Elliot S. Valenstein, University of Michigan. 1974. 407 pages \$10.95

Standards for Educational and Psychological Tests

1974 revision.

Developed under a grant from the Russell Sage Foundation by a joint committee of members from the APA, the American Educational Research Association, and the National Council on Measurement in Education.

This current revision of **Standards** is directed equally toward establishing guidelines for test developers and test users. It proposes *essential*, *very desirable* and *desirable* considerations for the effective development and use of standardized tests. Additionally, each standard is accompanied by an exemplary or clarifying comment. 80 pp. \$3 to APA, AERA, and NCME members; \$5 to nonmembers.

Contents:

Introduction

Standards for Tests, Manuals and Reports

Standards for Reports of Research on Reliability and Validity

Standards for the Use of Tests

Please note that payment must accompany all orders amounting to \$15 or less except for those orders submitted on institutional purchase order forms.

Thesaurus of Psychological Index Terms

Contains over 4,000 terms representing an authoritative, unambiguous, and hierarchically structured vocabulary used by psychology and related disciplines. This vocabulary will facilitate precise content representation of concepts described in psychological literature and allow for more flexibility in automated search and retrieval operations. These two factors promote more effective communication of psychological concepts in original works and research, ultimately aiding the content of publications to be focused in accordance with the interest patterns of psychologists.

This **Thesaurus**, developed by the Psychological Abstracts Information Services, is divided into three sections:

The **relationship section** shows the relationships among concepts that are associated with each other. Term relationships noted are: synonymous, broader, narrower, or related.

The **alphabetical section** presents each preferred term in alphabetical order, enabling rapid identification of terms used for indexing.

The **hierarchical section** contains 17 broad content areas in which terms are presented in descending order according to breadth of concept represented. The 17 categories correspond to major classifications used in *Psychological Abstracts*.

The relationship, alphabetical, and hierarchical sections will assist the user in selecting appropriate terms for different uses.

Administrators

- determine areas of research for an organization
- assure representative expertise in personnel selection

Researchers and Authors

- find synonyms for a term representing a concept
- select terms that represent a concept
- define subject matter topics for a paper or book

Educators

- structure a curriculum
- use as a tutorial aid

Consultants

- search the literature
- aid in retrieval of information

Librarians

- provide access to psychological literature
- aid in cataloging psychology material
- aid in ordering new psychological literature

Students

- locate concepts relevant to psychology
- focus areas of study

The **Thesaurus** contains 350 pages with a hard-cover and costs \$12. Please note that all orders amounting to \$15 or less must be accompanied by full payment except for those orders submitted on institutional purchase order forms.

Keller's Personalized System of Instruction: An Appraisal

Bruce A. Ryan, author; *Foreword* by Fred S. Keller. Offers the reader an objective assessment of the relevance of behavior theory, the role of unit tests, the appropriateness of the student proctor, and the success of self-evaluation in this increasingly popular approach to college-level education. In addition to an analytical review of the current literature, future directions for PSI are proposed and an invaluable "how-to" bibliography is included. 1974. 32 pp. \$2.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions.

Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the Journal, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this Journal may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness.

Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

Copyright © 1974 by the American Psychological Association, Inc.

Subscriptions: Subscriptions are available on a calendar-year basis only (January through December). Nonmember rates for 1974: \$12 domestic, \$13 foreign, \$2 single issue. Write to Subscription Section, APA. **Reprints:** Authors may order reprints of their articles from the printer when they receive galley proofs. **Back Issues and Back Volumes:** For information regarding back issues or back volumes write to Order Department, APA. **Microform Editions:** For information regarding microform editions write to any of the following: Johnson Associates, Inc., P.O. Box 1017, Greenwich, Connecticut 06830; University Microfilms, Ann Arbor, Michigan 48106; or Princeton Microfilms, Princeton, New Jersey 08540. **Change of Address:** Send change of address notice and a recent mailing label to the attention of the Subscription Section, APA, 30 days prior to the actual change of address. Undelivered copies resulting from address changes will not be replaced; second-class mail is not forwarded unless subscribers notify the local post office in writing that they will guarantee second-class forwarding postage. Published monthly in one volume, 12 issues, by the American Psychological Association, Inc., 1200 Seventeenth Street, N.W., Washington, D.C. 20036. Printed in the U.S.A. Second-class postage paid at Washington, D.C., and additional mailing offices.

The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

Psychology and the Lie Detector Industry

DAVID T. LYKKEN *University of Minnesota*¹

Polygraphic interrogation—the use of the so-called “lie detector”—is already a thriving industry in the United States, and it is growing rapidly. Several *million* polygraphic examinations are conducted annually by more than 3,000 professional polygraphers, most of whom are engaged in the private practice of their art, and some dozen schools, including one operated by the U.S. Army, are spawning graduates. This great crescendo in what for years had been a rather muted theme resulted, like most such booms, from newly discovered possibilities for profit. Estimates of losses due to employee theft in American business are running as high as \$6 billion annually; thus, a rich and eager market beckons the entrepreneur who claims to have a quick and relatively inexpensive method of detecting peculators. During the 1960s, the federal government invested large sums of money in a search for a *covert* lie detector, that is, a method of measuring physiological arousal in a subject who is unaware that his autonomic reactions are being monitored. This hope has now been realized with the development of the Psychological Stress Evaluator (Dector Corporation), a device that can detect emotional modulations of the speaking voice and thus can be applied even to tape recordings of telephone conversations and other “bugs.” Movements are afoot in most of the 50 states to license polygraphers, legitimating the profession by statutory fiat. Should the hopes of some of the leaders of this profession come to pass, polygraphic interrogation may soon become the most important area of applied psychology, both economically and in terms of social impact.

It is clear that polygraphic interrogation is an area of applied psychology because the lie de-

tector clearly is a psychological test. If persons who administer and evaluate Stanford-Binets or Rorschachs or MMPIs are psychometrists, then the polygrapher is a psychometrist also, and one basic science that should underlie his art is the science of psychological assessment. Since the polygraph test involves the study of autonomic (rather than verbal or other operant) responses to psychological stimuli, a second basic science area which is directly relevant to polygraphy is psychophysiology. One might therefore suppose that most polygraphers are trained psychologists, or at least that most polygraphers are trained *by* psychologists, or at the very least that a sufficient number of psychologists keep in touch with developments in the polygraphy business to provide expert guidance, for example, to courts or to legislative bodies. In fact, however, the field of polygraphic interrogation is about as well integrated into psychology as is the field of chiropractic into medicine; few professional polygraphers have any significant psychological training, and nearly all have received their training in polygraphy from teachers whose own prior professional background, if any, was in law enforcement. If bills were to be introduced tomorrow simultaneously in the legislatures of the 50 states limiting, regulating, or expanding the use of the lie detector, it is doubtful that more than some half dozen of those legislatures could find within the borders of the state a certified psychologist competent to offer expert testimony on the matter. This article is motivated by the conviction that such a situation is a kind of scandal, that psychologists *ought* to know about the lie detector because its use or misuse has social consequences potentially more important than anything most psychologists *do* know about *qua* psychologists, and that the “truth about the lie detector” is a matter of considerable intrinsic interest anyway. (For background information, the reader is referred to the historical survey by Trovillo, 1939, and two representative texts by Lee, 1953, and Reid & Inbau, 1966.)

¹ This work was supported in part by U.S. Public Health Service Grant MH18856-04 and by research funds from the State of Minnesota.

Requests for reprints should be sent to David T. Lykken, Box 392, Mayo Hospitals, University of Minnesota, Minneapolis, Minnesota 55455.

Methods of Polygraphic Interrogation

There are two fundamentally different methods of polygraphic interrogation, one which is properly called *lie detection* and another which I shall refer to as the *guilty knowledge test*. Since this basic and important distinction is for some reason not generally recognized, it will be elaborated with some care at the outset. There is no great mystery about the first category; any interrogation technique that involves asking the subject one or more relevant questions ("Did you kill Cock Robin?") and then attempting to determine by some method or combination of methods whether his answer to that question is or is not deceptive can be classified as a method of lie detection. There are a number of lie detection methods that differ in the nature of the questions used, the manner in which the questions are put to the subject, the sorts of data included in the analysis, and the methods of analysis employed. It is probable that more than 90% of all polygraphic examinations given in the field employ lie detection methods exclusively. Guilty knowledge detection, as the name implies, is intended to determine whether the subject is aware of certain information; the guilty knowledge test might be used whenever the demonstration of such awareness might, for example, differentiate between a guilty and an innocent suspect.

To illustrate both of these methods in the context of criminal investigation, I shall use a notorious case that occurred some years ago in New York City. The bass player in the band at the Stork Club was arrested on the charge of armed robbery, accused of having held up a number of Manhattan liquor stores and a loan company. The prosecution's case was based entirely on the fact that each of the victims positively identified the musician as the man who had threatened them with a gun and taken their money. After the usual protracted delays, the case went to trial, but before that ordeal was finished the sudden death of the judge resulted in a mistrial. After further delay and a second trial, the musician was found guilty as charged. Just before he was to be transferred to the state prison, another man, remarkably similar to the bass player in physical appearance, was arrested for armed robbery and volunteered a confession which exonerated the musician. By this time, more than two years after his initial arrest, that unfortunate victim of circumstance had lost his job, his home, his life savings, and even his wife, who had succumbed to

the strain and been committed to a state hospital.

Let us suppose that our protagonist had been given a polygraphic interrogation by the New York City police soon after his arrest. Had this happened, the method employed would almost certainly have been some form of lie detector test; that is, he would have been asked "critical" questions of the form, "Did you rob the Friendly Loan Company?" and the autonomic responses accompanying his "No" answer would have been compared with his responses to other "irrelevant" or "emotional control" questions. Based on this comparison and on the examiner's observation of the suspect during the examination and on whatever the examiner happened to know about the facts of the case, the polygrapher would have arrived at a global assessment: "deception indicated" or "deception not indicated" or "indeterminate." We shall examine these lie detection methods in more detail later, including the assumptions on which they are based and the evidence that exists concerning their validity. For the moment, let us assume that the polygrapher happened to arrive at the correct diagnosis in this instance, that the musician was telling the truth and was in fact innocent. It is possible that such a finding might have led the investigating officers to reexamine their evidence, perhaps to make a greater effort to corroborate whatever alibies the suspect might have been able to produce for the times in question. But in this particular case, with such an array of positive eyewitness identifications, it seems probable that the bass player's fate would not have been greatly altered by the lie detector test.

The Guilty Knowledge Test

Suppose, however, that the polygraphic examiner had been more sophisticated than most and had recognized that this case was one that lent itself nicely to the use of the guilty knowledge test. At the cost of some initial effort and preparation, and with the cooperation of the investigating officers, the examiner might have prepared a test along the following lines:

Item 1. The man we're looking for held up a loan office in Manhattan. If you're the guilty party, you will recognize the name of that loan company. I'm going to name a few loan companies that have offices in the vicinity; you just sit there quietly and repeat the names after me as you hear them. Was it the Ideal Loan Company? . . . Was it the Continental Loan Company? . . . Was it the Guarantee Loan Company? . . . Was it the Friendly Loan Company? . . . Was it the Fidelity Loan Company?

If the subject is in fact guilty of the robbery and if he did notice the name of the company he robbed, then it is a safe assumption that he will show a greater autonomic response to the guilty alternative ("Friendly Loan Company?") than he would if he did not possess this guilty knowledge. If we can further assume that he cannot deliberately but covertly produce an augmented response to one of the other alternatives in order to mislead the examiner and also that he has no other reason to respond selectively to one of these others, then we can expect that his response to the guilty alternative will at least be stronger than his mean response to the array of alternatives and probably that it will be strongest of all. On the other hand, if the subject is in fact innocent and if he has no indirect means of knowing or inferring which alternative is "correct," then we can safely suppose that there is only about one chance in five that his largest autonomic response will be to the guilty alternative.

Item 2. Before showing his gun, the robber pretended that he wanted to take out a loan for a certain purpose. If you're the guilty man, you will know whether that purpose was to buy a car, to pay doctor bills, to pay for a vacation trip, to buy a color TV, or to get a present for his wife. I'm going to name each of these five possibilities in order and I want you to sit quietly and just repeat what I say. Was it—a car? . . . [etc.].

If the subject had been guilty, it is very likely that he would have remembered talking to the woman at the loan office about needing money to pay his "doctor bills" and therefore that his autonomic response to this one of the five alternatives would be augmented by this guilty knowledge. On the other hand, the probability that an innocent suspect would give his largest response to this alternative is only about .2. Similarly, the probability that an innocent suspect might happen to respond most strongly to the "correct" alternative in *both* Item 1 and Item 2 would be equal to the product of the individual item probabilities, or about .04.

Item 3. If you did rob this loan company, you will recognize the woman you talked to, the one who gave you the money. I have some photographs here of women tellers in five different loan offices, just as they look to a customer. I will show these pictures to you one at a time. Just sit there quietly and look at each photograph.

The probability that an innocent suspect might chance to "hit" on all three items would be approximately $(1/5)^3 = .008$. Because subjects tend to respond more strongly to the first alternative in any list, the examiner might make a practice of using an extra "incorrect" alternative at the start of each set and then ignoring the response to that alterna-

tive. With only 10 such guilty knowledge items, each with five scorable alternatives, there would be only about 1 chance in 10 million that a subject without guilty knowledge would give his largest response to the "correct" alternatives in all 10 items. With a 10-item test, the actual culprit would only have to "hit" on 6 of the 10 items to permit us to say that the chances are less than 1 in 1,000 that he is innocent.

In the case of the misidentified musician, it would have been a relatively simple matter to construct several tests of 10 items each, taking advantage of the fact that in this situation one could be sure that the guilty suspect would possess a great deal of guilty knowledge about the details of the several crimes of which he was accused, details that would not be known to an innocent suspect but that could be determined with a little effort and competent investigation and planning prior to the examination. Moreover, of course, each set of items could be used more than once; the probability that the "correct" alternative would elicit the largest response from an innocent subject on both of two separate testings is doubtless greater than $(1/5)^2$ because that alternative might have been especially provocative for him on both occasions even without guilty knowledge, but the probability that the first test *and* the retest will *both* be false-positive is certainly smaller than .2. Therefore, after testing our unfortunate bass player, the examiner would have been able to inform the prosecution that the chances of this man's being guilty were vanishingly small and that the police should be deployed again to seek some other suspect fitting his general description.

Assumptions and Limitations of the Guilty Knowledge Test

The guilty knowledge method requires that the examiner be able to determine a number of facts that only a guilty subject will be able to recognize (these facts can be perfectly trivial matters which would not appear in newspaper accounts) and that he can present these facts in the form of multiple-choice items, embedded in a set of three or four or five alternatives that would seem equally plausible to an innocent subject without guilty knowledge. The basic assumption of the guilty knowledge test is that the guilty subject will show stronger autonomic response to what he recognizes as the significant alternative than he would have shown

without such guilty knowledge. The amplitude of the involuntary autonomic responses to the significant alternative has little meaning by itself; a hyperreactive subject might respond strongly to that alternative without knowing that it was the "correct" one, while a hyporeactive suspect might give a small response even though he does have guilty knowledge. But the same subject's responses to the other plausible but incorrect alternatives of the guilty knowledge test provide a nearly ideal control against which to evaluate his response to the significant alternative. In the language of psychophysiology, all of the guilty knowledge test alternatives can be expected to produce orienting reflexes that will vary in amplitude from subject to subject for a number of reasons, of which guilt is only one. However, for the guilty subject only, the "correct" alternative will have a special significance, an added "signal value" (Berlyne, 1960), which will tend to produce a stronger orienting reflex than that subject will show to the other alternatives. Whether he is high or low in reactivity, whether he has confidence in the test or not, whether he is frightened and aroused or calm and indifferent, we can still expect that his response to this significant alternative will be stronger than to the other alternatives as long as he recognizes which alternative is "correct." Similarly, if he has no guilty knowledge, neither his reactivity, his present emotional state, nor his confidence in the validity of the test can act to influence his guilty knowledge test score. For *all* subjects who are without guilty knowledge, the probability of the "correct" alternative producing the largest response on each of the N test items will be $(1/K)^N$, where K is the number of alternatives per item (assuming sequential independence of the items and well-chosen item alternatives).

Finally, since the guilty knowledge method does not require that the items be in the form of questions to which the subject must give answers, that is, since he can be asked merely to repeat the alternative or, even, to simply sit and listen, the interesting question arises as to whether requiring a criminal suspect to submit to a guilty knowledge test would involve a violation of his Fifth Amendment rights any more than would requiring him to show his face to a witness or to submit to fingerprinting.

On the other hand, the guilty knowledge method simply cannot be used in many situations in which the lie detector is now used, and it almost always will require much more careful preparation and pre-

investigation than does a lie detector test. Moreover, even where it is appropriate, it is obvious that the construction of a good multiple-choice guilty knowledge test requires considerable ingenuity and psychological sensitivity. Where it is applicable—where the requisite guilty knowledge information is available to a competent examiner—there can be little doubt that the guilty knowledge method could be a powerful tool in criminal investigation and that its greatest benefit might be to protect innocent suspects from prolonged police harassment and even false imprisonment.

But it must be emphasized that the guilty knowledge method is *not* in fact employed by professional polygraphers, partly because the distinctive character of the method has not yet been understood. Even the two recent reviews written by psychophysicists (Barland & Raskin, 1973; Orne, Thackray, & Paskewitz, 1972) failed to distinguish between lie detection and guilty knowledge methods with adequate clarity. One problem here is a tendency to regard the guilty knowledge method as just a variant of something known to polygraphers as the *peak of tension test*. As it is commonly described in polygraphy literature (e.g., Reid & Inbau, 1966), the peak of tension test involves presenting a series of questions, only one of which is expected to elicit a lie from a guilty subject, after first showing the subject what the sequence of questions is to be. The test gets its name from the notion that a guilty suspect will show increasing autonomic arousal in anticipation of the critical question, a peak of tension when that question is answered deceptively, and a decline thereafter. But this is nothing more than a standard lie detector test embellished by the opportunity to look for a predictable trend or peak in tonic level of autonomic function in addition to whatever information is provided by the phasic autonomic responses to the individual questions.

As it is described by other authorities (e.g., Barland & Raskin, 1973), the peak of tension test resembles a single-item guilty knowledge test. However, there seems to be no clear awareness that it is a very different thing to use the polygraph to determine whether the subject can identify the significant alternative, than to use autonomic arousal or "tension" as evidence that the subject is lying.

With a very few exceptions (e.g., Ben Shankhar, Lieblich, & Kugelman, 1970; Davidson, 1968; Lykken, 1959, 1960), the literature on polygraphic

interrogation deals exclusively with lie detection methods. The professional practice of polygraphic interrogation employs lie detection methods almost without exception, and it should be clearly understood that the guilty knowledge method *could not* be used in the vast majority of situations where the lie detector is now used—many criminal investigations and *all* employee screening applications—because of a lack of the guilty knowledge information necessary to construct the item set. Therefore, the several virtues of the guilty knowledge method—the fact that it rests on reasonable assumptions, that it can produce an objective, quantitative estimate of the probability of guilt, and that in certain situations it is capable of yielding near-perfect validity—cannot be marshaled in support of current practices.

The Lie Detector Test

The usual field polygraph makes continuous recordings of three channels of physiological data. The electrodermal channel displays changes in palmar skin resistance or galvanic skin response (GSR), usually by means of a capacity-coupled bridge circuit which results in the loss of any information about tonic resistance levels. The "cardio" channel is actually an arm plethysmograph which records changes in upper-arm volume associated with the cardiac cycle. From this channel, one can determine heart rate and some indication of changes in pulse volume. The third channel is driven pneumatically or electrically from an expansible belt around the subject's chest and records respiration. The field polygraph as manufactured for the lie detector trade is approximately 20 years behind the state of the art as represented by the modern psychophysiological laboratory. While not very important in itself because the problems with lie detection devolve from logical and psychological considerations rather than from questions of psychophysiological technique, this obsolescent character of field polygraph design is symptomatic of the fact that polygraphic interrogation has developed in virtual isolation from the original parent discipline of psychophysiology.

The Psychological Stress Evaluator, mentioned earlier, adds a fourth channel that records the presence of a low-frequency component present in normal speech sounds but said to diminish under emotional stress. Assuming that these claims can be corroborated independently, the Psychological Stress Evaluator represents an ingenious technologi-

cal advance having the unique advantage of being usable without the subject's knowledge. But the questions to be raised here about the logic and validity of the lie detector are not concerned with the nature of the response being monitored and would seem to apply equally to the Psychological Stress Evaluator as to the traditional polygraph.

The standard lie detector test is normally preceded by a pretest interview in which the list of questions to be used is gone over with the subject to be sure that he understands the wording and feels he can answer them truthfully and unambiguously with a simple yes or no. Another purpose of the pretest interview is to indirectly convince the subject that the lie detector really works, that he has nothing to fear if he is innocent and truthful, but that any attempt at deception will be detected easily. After the preliminary conversation, the subject is seated in the examining room and the transducers are attached to his hand, arm, and chest. The agreed-upon list of questions is presented, usually two or three times, and the examiner may engage in some discussion with the subject between testings in order to insure that the questions are unambiguous and that, for example, the subject is not responding to a critical question for some unsuspected but irrelevant reason. Although I have not seen it recommended in published manuals, one may suppose that professional examiners frequently suggest to subjects that their attempts to deceive have in fact been detected (whether they have or have not) with the intent of precipitating a confession from a guilty subject. It is a fact that the lie detector functions effectively as a "painless third degree" and that the confessions of guilt elicited in this situation might themselves provide sufficient economic justification for its use by the police, even if the technique were wholly invalid and the polygraph merely a stage prop.

The question list used would consist of from 5 to 10 questions that can be answered yes or no. It would include one or more "critical" or "relevant" questions of the form, "Did you fire the bullet that hit Jones?" and one or more "irrelevant" questions pertaining to unrelated and unexciting matters, for example, "Are you sitting down?" Most modern polygraphers also include several control questions which are intended to serve as emotional standards. The control question should be unrelated to the matter under investigation, and it is expected that the subject will answer it truthfully; however, the

control question is chosen with the intention that it will elicit an emotional response from the subject, preferably a response involving an attitude of guilt, for example, "Can you remember ever stealing anything before you were 18 years old?" Finally, some examiners try to include a "guilt complex" question, for example, a question relating to some other real or imaginary crime of which the subject is innocent.

Methods of evaluating lie detector tests to determine whether deception is or is not indicated—that is, whether the test has been "passed" or "failed"—vary from one examiner to another. Some of the early workers maintained the concept of a specific lie response, that is, the notion that some unique pattern of autonomic response exists that is manifested by all individuals when they are deliberately lying but not when they are answering truthfully, even though fearfully. Thus, Benussi (1914) claimed that the respiratory ratio of expiration to inspiration increases after lying but decreases after a truthful answer. Marston (1938) believed that an increase in systolic blood pressure was certain evidence of lying. Summers (1939) contended that the arousal produced by the critical questions diminishes (habituates) with repetition if the subject is innocent but not if the subject is lying. All that we know about individual differences in both psychological and physiological response tendencies argues against the possibility that there is such a specific lie response, and since no acceptable evidence has been forthcoming in support of these early claims, such methods of analysis have fallen into disuse.

The modern polygrapher simply looks for evidence of autonomic disturbance associated with the answer to the critical questions, disturbance that is more intense or persistent than that associated with the irrelevant questions, and, especially, the emotional control questions. Most examiners make a global evaluation, without specific measurement or scoring. At least one of the schools now training polygraphic examiners teaches the *zone of comparison technique* (Barland & Raskin, 1973) in which a numerical score is derived from specified comparisons of responses to the several types of question. A high score results from a record in which the autonomic perturbation associated with the critical questions is much more persistent and intense than that associated with the control questions, and the examiner is advised to classify tests that give intermediate scores as "inconclusive."

A point that must be emphasized, however, is that the professional polygrapher almost never arrives at his final diagnosis on the basis of the polygraphic records alone; the examiner, rather than the polygraph, is the actual "lie detector." Laboratory studies often employ "blind reading" of charts by judges who know nothing else about the subject or the circumstances, and a similar practice is occasionally followed in the field. But in the vast majority of field examinations, the final diagnosis results from a subjective blending in the mind of the examiner of what he has observed in the charts, in the demeanor of the subject during the test, and in the preexamination interview, what he knows of the evidence against the suspect and what he may infer from the suspect's prior history, and even any prejudices he may hold about the subject's race, age, appearance, and the like. Thus, it is a fact that evidence which might be collected relating to the validity of diagnoses arrived at in this standard manner can only be interpreted as evidence relating to the performance of the particular examiner studied and is almost completely uninformative concerning the objective contribution of the polygraphic data.

Assumptions of the (Autonomic) Lie Detector Test

As we have seen, the basic assumption of the guilty knowledge test is straightforward and reasonable; given an array of stimuli, X, Y, and Z, a guilty suspect who recognizes that Z is related to the crime in question will tend to show a different autonomic response—a stronger orienting reflex—to Z than to X or Y. The assumptions underlying the lie detector test are considerably less straightforward and not nearly so easily accepted. First of all, most professionally administered lie tests are influenced to an unknown degree by the examiner's impressions of the subject and the available evidence, interacting with his evaluation of the actual polygraph record. For present purposes, we shall confine our attention to the latter, to what might be called the autonomic lie detector test, in order to evaluate the assumptions involved in a lie test scored by someone unfamiliar with the accused or with the case against him, working from the polygraphic data solely.

It is a characteristic of the lie test that the "critical question" (e.g., "Did you do it?") is obviously "relevant" to all subjects, guilty and inno-

cent alike. It will therefore tend to elicit an emotional response and the attendant autonomic reaction in the guilty and innocent alike. It is perfectly reasonable to suppose that being guilty and attempting to deceive will tend to add an increment to the autonomic response of guilty, as compared to innocent, subjects. Thus, one might readily imagine that the response to the critical question of 1,000 guilty suspects will tend, on the average, to be larger than the mean response of 1,000 innocent suspects. However, it is also clear that the magnitude of this response will not be determined solely by the fact of guilt or innocence. Other things being equal, a highly reactive or labile subject will respond more strongly to the same stimulus than will a subject whose lability is low; the critical response magnitude depends partly on individual lability, L , independently of guilt or innocence. Similarly, individuals will differ in their emotional attitude toward the same situation, in their *fear* of the consequences of being found guilty. Thus, for some people, the prospect of being tried, convicted, and punished for the crime in question may seem catastrophic, while for others, for example, those who have less to lose in such an eventuality, finding themselves in the role of a criminal suspect may be much less fear inducing. Individual differences in fear of the consequences, F , will therefore also help to determine the critical response, independently of guilt or innocence. Finally, another important determinant will be the subject's confidence in the validity of the test procedure. If he is perfectly confident that the test will yield the correct result (i.e., if $C = 1.0$), then the guilty suspect will tend to show his maximum response because he "knows" that his guilt is about to be demonstrated. An innocent subject with perfect confidence, on the other hand, will tend to show a minimum response; no matter how labile he may be or how abhorrent conviction and punishment might seem to him to be, he "knows" that he is about to be exonerated, and he responds to the critical question calmly and without great apprehension. The preexamination interview of the standard lie test is designed in part to inspire such confidence in the subject; the extent to which this works—the extent to which C approaches unity at the time the critical question is presented—will obviously also vary independently of the fact of guilt or innocence.

These three variables, extraneous to guilt or innocence, which however also interact to determine the magnitude of response to the "critical" lie test

question, can be conveniently summarized in a formula. For clarity, we shall use separate formulas to represent the response of Mr. I, who is innocent and telling the truth, and the response of Mr. G, who is guilty and lying.

$$R_1 = L_1 F_1 \left(\frac{1 - C_1}{2} \right) + M_1 \quad [1]$$

$$R_2 = L_2 F_2 \left(\frac{1 + C_2}{2} \right) + M_2 \quad [2]$$

where R_1 is the critical response of an innocent suspect, Mr. I; R_2 is the critical response of a guilty suspect, Mr. G; L is the subject's autonomic reactivity or lability; F is the subject's fear of the consequences of being found guilty; C is the subject's confidence in the validity of the lie test ($-1 < C < +1$); and M is the minimum orienting response which any stimulus might elicit in that subject. (While these formulas will be helpful in summarizing the ensuing argument, readers who tend to go faint at the sight of an equation will find that they can ignore the algebra and still be able to follow the discussion.) Note that in the two equations above, the variables L and F function multiplicatively; if either the subject's lability or his fear of the consequences happens to be zero, then his response to the critical question will be a minimum (M), irrespective of his degree of confidence in the test or of whether he is guilty. Note also that C , the measure of degree of confidence, functions differently for a guilty than for an innocent subject. If $C = 1.0$, an innocent suspect will give a minimum response ($R_1 = M_1$), while a guilty suspect, under these conditions, will give a maximum response ($R_2 = L_2 F_2 + M_2$). That is, Formulas 1 and 2 merely summarize the commonsense ideas already advanced and contain no appreciable "surplus meaning" deriving from the algebra.

Since a subject's response to the critical question in the lie test can be affected by (is a function of) several factors which will vary from subject to subject independently of who is guilty and who is not, it is clearly not possible to say with any confidence that a critical response larger than some specified magnitude is certain evidence of guilt. A truthful, innocent suspect who happens to be unusually labile and who feels that being prosecuted for the crime in question might ruin his career could obviously give a stronger emotional and autonomic response to the question, "Are you guilty?" than a psychopathic, guilty suspect whose lability is low and who does not really care whether he "fails"

the test or not. The absolute magnitude of the critical response could provide a basis for a high-validity lie test *only* if one could be sure that *all* subjects had nearly perfect confidence ($C = 1.0$) that the test *was* valid (because, for example, truthful subjects would then all show just the minimum response). On the other hand, when confidence is zero—that is, when subjects believe that their passing or failing will be determined as by flipping a coin—then the formulas agree with common sense in indicating that the actual validity of the test will then *be* zero.

Assuming that the best one could hope for would be that *most* subjects could be led to have at least *some* confidence in the lie test, the remaining problem is to find a way to control for individual differences in the variables L and F which will act to influence the critical response independently of guilt or innocence. It will be recalled that, in the guilty knowledge test, the response to the "correct" alternative will also be influenced by these same variables, autonomic lability and fear of the consequences of "failing" the test. But these same variables also affect the responses to the "incorrect" alternatives which therefore provide the necessary control; by subtracting the mean response to the "incorrect" alternatives from the "correct" response, one can estimate the increment added by the guilty subject's recognition of the "correct" alternative. In other words, in the case of the guilty knowledge test, the responses to the "incorrect" alternatives provide an excellent estimate of the response which *that subject* would be expected to make to the "correct" alternative *if he is in fact innocent*.

How might one devise an equally acceptable control question for the lie detector situation, a question that could be expected to elicit a response which is a good estimate of the response which *that subject* could be expected to make to the "critical" question *if he is in fact innocent*? An ideal situation could be imagined along the following lines. Suppose that our subject is suspected of being guilty of crime X. As far as he knows, he might equally well be suspected of crime Y, which carries penalties of the same degree of severity as crime X. However, unknown to the subject, we happen to have certain evidence that he is *not* guilty of crime Y. Under these rather special circumstances, the subject's response to the control question, "Did you commit crime Y?" provides us with a good estimate of how that subject might be expected to respond to the critical question, "Did you commit

crime X?" if he is innocent of crime X. In terms of the foregoing formulas, we can express the difference between these two responses as follows:

Expected "lie score" if innocent

$$= R_x - R_y = \left[LF \left(\frac{1-C}{2} \right) + M \right] - \left[LF \left(\frac{1-C}{2} \right) + M \right] = 0. \quad [3]$$

Expected "lie score" if guilty

$$= \left[LF \left(\frac{1+C}{2} \right) + M \right] - \left[LF \left(\frac{1-C}{2} \right) + M \right] = CLF. \quad [4]$$

That is, the difference in magnitude of the critical and control responses would be expected to average about zero for an innocent subject, but for a subject who is guilty this difference would be expected to vary directly with the product of L , F , and C , that is, with his autonomic lability, his fear of being prosecuted, and his confidence in the validity of the lie test. As long as none of these individual difference variables is zero, the guilty might be expected to be well differentiated from the innocent with this form of lie test.

But the lie detector test actually employed in the field does not use the sort of control question we have been supposing here. Instead, the critical response is compared with that subject's response to the so-called "emotional control" question, of the form, "Did you ever steal anything before you were 18 years old?" The subject is expected to reply truthfully to this question, and all that is required of the question is that it should produce for this subject some sort of emotional response. But clearly this response is not an adequate "control" at all. In the terms of our formulas, although the autonomic lability term L should apply equally to the "control" as to the critical response, it would obviously be nonsensical to imagine that the fear variable F could be equilibrated for the two questions. How could one undertake to ask Jones a question, to which he will answer truthfully, that would be neither more nor less fearsome or disturbing to Jones than will be the critical question, "Did you rape Miss Fisbee?" so that his response to the former question will serve as a reasonable estimate of how he would respond to the latter *if innocent*? It is equally difficult to imagine how one might design such an "emotional control" question in response to which the confidence variable C would play the same role that it plays in the critical re-

sponse. In short, the standard lie test in which the "lie score" is a function of the difference between the responses to the critical and "emotional control" questions can only be said to provide some degree of control for individual differences in autonomic lability; the "lie score" will continue to vary, not only with respect to differences among subjects in their confidence in the procedure, but also with individual differences in the relative emotionality or fearfulness of the critical and control questions.

As was indicated in the preceding section, some professional polygraphers do make use of what is called a "guilt complex" question as an additional control. The rationale for this procedure in the polygraphy literature is somewhat ambiguous or vague, but it does appear that at least some field polygraphers do sometimes try to formulate a question relating to a real or imaginary crime of which the subject is known to be innocent. On its face, the guilt complex question obviously comes closer to the sort of control recommended earlier for the lie detector test, but there are several reasons for being dubious about this. First, the guilt complex question always seems to be used together with emotional control questions as discussed above and treated in the scoring procedure as if the two were equivalent, a practice that would not seem to inspire confidence. Second, one does not find in the literature any discussion of the rather formidable problems that must be dealt with if the guilt complex question is to serve its control function, that is, to produce a response that is a reasonable estimate of what the critical response should be if the subject is innocent and answering truthfully. It will be recalled from my earlier example that the control question, concerning crime Y, will provide an adequate control only (a) if the subject regards crimes X and Y as similar and prosecution for either as equally serious, and (b) if the subject believes that he is equally and independently suspected of both crimes and that he is therefore truly in jeopardy of being prosecuted for Y even though innocent of that crime. Now, it is possible to imagine a field situation in which such a control might be established, but it is abundantly clear that this would *not* be possible in most situations in which the lie detector is used (the emotional control question is always feasible but has the important defect that it cannot be expected to work very well). Moreover, if it were to become known that the standard lie detector examination had the crime X versus crime Y format, criminal suspects

could be expected quickly to identify which question is "critical" and which is the "control," and the effectiveness of the procedure will be forfeited as soon as that happens.

To summarize this section, we have seen that the autonomic response to the critical question will always be influenced by individual difference variables which are not a function of the subject's guilt or innocence. Therefore, if it is to have any hope of high validity, the lie detector test must provide a means of comparing the actual critical response to some reasonable estimate of what that subject's critical response would be if he were innocent. Such a control is an integral part of the guilty knowledge test, but that test can only be used in a limited proportion of criminal cases and is apparently never used by field polygraphers. We have seen that the emotional control question commonly used in the field does not provide the reasonable estimate required. Under very special circumstances, in which the subject can be persuaded that he is also and independently suspected of a second crime of which he is actually innocent, then his response to a question about this crime might provide the needed estimate. However, this specific method is seldom if ever used by field polygraphers, it could be used properly only in a limited proportion of cases, and it would quickly become invalidated if it were to come into standard use.

The purpose of the foregoing analysis has been to provide a basis for estimating the prior probability of the claim that conventional lie detection methods have extremely high validities, for example, 92% (Bersh, 1969), 99% (Arther, 1965), or 100% (Kubis, 1950). There can be little doubt that professional polygraphy has a validity significantly, even substantially, better than chance, but for reasons that will become apparent later, the important question about the lie detector is not whether its diagnoses are more valid than could be achieved by flipping coins but rather whether they are very nearly infallible, as the professionals claim. If the decision to amputate a leg is to depend entirely on the result of a test for osteosarcoma and if only 10% of those tested actually have the disease, then the difference between a test that is 80% valid and one that is 92% or 99% valid may be all the difference in the world. The true validity of the lie detector is, of course, an empirical question, but it would be naive to suppose that such empirical questions are easily answered. If the a priori likelihood were high that the validity of the

lie detector was 90 or better, then one or two studies yielding such an estimate empirically might be considered adequate even though each study might be found to be defective in some way. What I have attempted to demonstrate is that the prior probability of such high validities for lie detection methods is in fact vanishingly small, and therefore, as in the case of ESP, for example, we are entitled to require unusually strong, clear, well-replicated evidence before accepting the fact in the face of the theory. As we shall discover in the next section, such evidence is wholly lacking.

Empirical Evidence of Lie Detector Validity

Estimates given by professional polygraphers on the basis of their own experience are essentially worthless. This dogmatic pronouncement is not intended to disparage the integrity of these professionals, most of whom in my experience are honest and able people. But when one considers what would be required to support an accurate estimate of this sort, one can see at once that these conditions are simply never met in practice. One of my acquaintances was trained by Leonard Keeler himself and has given thousands of polygraph examinations in a police setting over a span of more than 30 years. His "conservative" estimate of the cumulative validity of the lie test in his hands is 95%. But how could he know which of those thousands of tests produced correct results and which did not? In many instances, a court may eventually adjudicate guilt, but a courtroom verdict is hardly an infallible criterion, and, in any event, final legal disposition of such cases will typically occur months after the suspect has moved beyond the ken of the polygrapher. I know of no professional who even pretends to have kept up the elaborate bookkeeping system that would be required to follow up on all subjects interrogated. In a high proportion of cases, there will be no final disposition made at all; the vast majority of employee-screening interrogations are of this nature.

In a significant proportion of police interrogations, the guilty suspect will confess. When the confession is made after the lie test has been definitely evaluated (but not so long after that the polygrapher never hears about it), then one might generate an adequate estimate of validity for this very limited subset of cases, but subjects who will later confess are hardly representative of subjects in general, especially those who have *nothing to*

confess. Often, the confession will occur during the lie test or even in anticipation of it. Clearly, since no diagnosis has been made, none can be tested for validity in such instances, and yet one may be permitted to suspect that each such experience adds a bit to the examiner's subjective certainty that he is dealing with a useful and "valid" technique. One highly experienced polygrapher testified before the 1973 session of the Minnesota State Legislature that he had conducted more than 20,000 polygraphic interrogations and that he had "never once been proven to have made a mistake"; such testimonials should not be taken very seriously.

Laboratory studies cannot provide adequate validity estimates. This may be the only value judgment in the present article with which the majority of professional polygraphers would agree. Laboratory experiments involving mock crimes or other contrivances of even less ecological validity have commonly achieved a hit rate of from 70% to 85%, usually against a chance expectancy of from 20% to 50%. Professional examiners dismiss such studies as irrelevant parlor games and insist, reasonably, that in a police investigation, with real crimes and real punishments, the results might be altogether different and the hit rates much higher. Since this coin has two sides, one should also point out that moving from the laboratory to the field situation might also serve to *lower* hit rates. While a guilty suspect may indeed be more apprehensive and hence more reactive when interrogated in the jail than will a mock-guilty college sophomore in the laboratory, it is also true that the innocent suspect will be more reactive in the real-life situation and, thus, more likely to become a false-positive.

Adequate criteria against which to measure lie test validity are next to impossible to obtain in the field. Although slightly less dogmatic than the previous two, this proposition is stated strongly enough to emphasize that, while field investigations are the only trustworthy source of estimates of lie detector validity, it is exceedingly difficult in the field to establish an adequate criterion of whether the lie test diagnosis was in fact correct. For this reason, only a single field study has so far been published in which this criterion problem seems to have been handled well enough for the data to be taken seriously. Bersh (1969) obtained records on a fairly large sample of criminal investigations conducted by the military in which a standard lie detector examination had been given to the (serviceman) suspect. Each complete case file (minus

only the polygraph findings) was evaluated independently by four attorneys from the office of the Judge Advocate General. These attorneys were instructed to "disregard all legal technicalities and to judge each case solely on the evidence . . ." Each judge was asked to eliminate cases in which he felt the evidence was insufficient and then to arrive at a positive determination of guilt or innocence on the remainder.

Using the unanimous verdict of the four-judge panel as a criterion, it was found that the polygraphers' diagnosis agreed with the criterion on 92.4% of 157 cases. On 59 additional cases for which only three of the four judges were in agreement, the hit rate was lower, 74.6%, possibly because the majority-agreement criterion was less valid than the unanimous-agreement criterion. As Bersh (1969) pointed out, polygraphic examiners in the military are undoubtedly better and more uniformly trained on the average than polygraphers generally, so that these findings probably represent the state of the art as favorably as possible.

This study is an important contribution to the literature in this field but, as Bersh himself indicated, the findings must be interpreted with caution. First of all, the 157 cases on which the polygraphers achieved the hit rate of 92.4% were a highly selected sample and, presumably, not representative even of the general run of polygraphic investigations done in a military setting. We know that another 59 cases produced a 3:1 vote of the panel (and only a 75% hit rate against a chance expectancy of about 50%), but we are not told in how many cases the judges split 2:2 nor, especially, how many of the original cases were discarded because one or more judges found the file data to be inadequate to yield a positive judgment. Most important, however, is the fact that *none* of these findings tell us anything definite about the validity of the polygraphic lie test itself because, as a matter of routine, the examiners had complete access to the case file—the evidence against the suspect—as well as any information that they could descry in the pretest interview, the subject's appearance and demeanor and the like, prior to the examination, and there is no way of determining the relative weights that were subjectively allotted to this information, as opposed to the polygraph records themselves, as the examiner arrived at his diagnosis. Since the validity criterion was a judgment based on the file records, a jaundiced appraisal of Bersh's findings might be that he has shown merely that

when four judges agree that the evidence indicates guilt or innocence, a fifth judge is very likely also to agree on the basis of the same data. Such an appraisal is probably unduly harsh: Bersh pointed out that the files were often less complete at the time of the lie test than when evaluated by the attorneys. Still, however, it has to be admitted that one cannot say with certainty that the polygraph charts contributed anything at all to the accuracy of the original diagnoses.

Summarizing this examination of the evidence for the validity of the lie detector, after eliminating from consideration the testimonials of experienced polygraphers and after eliminating also the results of laboratory studies which, while obviously useful in extending our understanding of these phenomena, cannot be safely used to estimate the validity of field testing, we find that we are left with exactly *one* good field study. And that one study, while it indicates that Army-trained examiners can apparently do very well indeed in determining the guilt or innocence of at least a subset of criminal suspects, unfortunately sheds no clear light on the validity of the autonomic-response portion of the lie detector test. It was contended in the previous section that the prior probability of the *autonomic* lie detector as having .90+ validity was so low that one might reasonably insist on especially clear, well-replicated evidence before accepting such a proposition. We see now that no such evidence exists.

Before continuing, however, it would be only fair to emphasize the important positive conclusion that can be drawn from Bersh's data concerning the validity of the *human* lie detector. In a criminal investigation situation, where the evidence against a suspect is suggestive but not yet overwhelming, and where that suspect still maintains his innocence, a well-trained polygraphic interrogator can in about one hour's time arrive at a diagnosis of guilt or innocence that is likely to be correct 9 times out of 10. It would be interesting to know whether that hit rate would be greatly reduced if the polygraph pens were to be activated by random-noise generators rather than by transducers connected to the subject. It would also be interesting to compare the polygrapher's hit rate against the validity of judgments made by an experienced policeman who had interviewed the suspect at about the same time, without benefit of the polygraphic props and ritual. But, in any case, it should be apparent that a method which can achieve such a degree of accuracy at so little cost could be of great benefit

both in increasing the efficiency of investigation and in protecting the innocent. When the polygrapher says "Guilty," all efforts can be concentrated on finding the physical evidence that will prove the suspect's guilt; when the polygrapher says "Innocent," those same efforts can be redeployed in another direction. As long as the polygrapher's diagnosis is regarded as tentative and advisory rather than as conclusive and the investigating officers remember that the polygrapher will be wrong perhaps 10% of the time, the use of this (human) lie detector can be of real social benefit.

The Lie Detector in Employment Screening

We turn now to a consideration of an area in which the guilty knowledge method *cannot* be used but where the use of the lie detector has grown so rapidly in recent years as to threaten to become a major industry—and a major influence on our society. This is the area of employee screening: preemployment screening of job applicants to determine who should not be hired and routine post-employment screening to find out who has been pilfering from the company during the preceding year. Just as the guilty knowledge method is fundamentally different from the lie detector, so too is the use of the lie detector in employee screening different in certain basic ways from the use of that same technique in criminal investigation by the police.

For purposes of comparison, consider the police investigation situation first. A crime has been committed and one or more likely suspects are to be examined. In the police situation, it might be reasonable for us to assume that the base rates for lying may be fairly high, perhaps approaching 50%, because the police will not bother to examine anyone who is not a "likely" suspect. In what follows, I am also going to make the unproven assumption that the overall validity of the conventional lie detector method is as high as 90%. Now if, over many police examinations of the type we are considering, 50% of the suspects do in fact try to lie, and if the lie detector is 90% valid, then we can expect to identify 45 out of every 50 liars, while only 5 of every 50 truth tellers will be incorrectly classified as liars, that is, will be false-positives. Such a result would obviously be very useful to the police and it could be achieved at relatively minor cost, assuming that lie detector results are never tolerated as evidence in court, because the only

harm done to the five false-positives will be that they will continue for a time to be the subject of intensive police interest and investigation. If we can assume textbook police work, with no beatings and no manufacturing of evidence, then we can suppose that "intensive police interest" will eventually flag after it has been unable to produce admissible physical evidence that these suspects are in fact guilty.

The first basic difference between police lie detection and the employment screening situation has to do with the question of the consequences of being a false-positive. The great impetus behind the growing use of the lie detector with employees is the enormous annual losses attributed to employee theft, so there is an understandable attraction in a relatively quick and cheap procedure which claims to be able to weed out potential thieves, drug addicts, and the like, before they are hired or to identify light-fingered employees in the annual screening. Since the main point of using the lie detector in this application is to save money, to save both the losses that would occur with no screening or the considerable costs of conventional private detective work or individual background investigations, one can see that these savings will be realized only if the lie detector is permitted to make the final decisions; if the examinee fails the lie test then he is not hired. Although one cannot send a man to prison for flunking a lie detector test, there are no constitutional guarantees which prevent him from being deprived of a job for the same reason.

Let me illustrate this particular problem with a recent real-life occurrence. An advertising agency in Minneapolis kept a \$6,000 movie camera in a locked cabinet. The camera was stolen without forcible entry and a local private detective agency urged that the four employees who had keys to this cabinet should be asked to take a polygraph test. The employees, who felt of course that they could hardly claim to be innocent and yet refuse to take the test, agreed to these plans; one of them clearly "failed" the lie test. This apparent culprit happened to be a young, black account executive who was doing so well with the company that they were reluctant to accept this verdict. The young man was sent back for a second test by a different examiner; again he "failed." A third test was conducted by the most experienced of the polygraphers and this one too resulted in a verdict of "probable deception." Just at the moment when the company

president had regretfully determined to fire this apparent thief, a fortuitous set of circumstances led a *fifth* individual, who had never taken the lie test, to confess that he had stolen the camera, completely exonerating the other suspect. Except for this lucky accident, that first young man would not now be holding a well-paying job, making good use of his considerable talents, but instead he would be out on the street, saddled with a history of having been fired from his previous employment for having failed a lie detector test, and with negligible hope of ever again finding work in his chosen profession.

But I want to emphasize a second respect in which the employee-screening situation differs fundamentally from that of criminal investigation. If 1,000 employees are given a routine annual polygraph examination and are asked whether they have stolen anything from the company during the preceding year, it would clearly be unreasonable to expect that as many as half of them will in fact lie. Nobody knows what the base rates for lying are in such a situation but I should think that 5% would be a reasonable figure. Now let us continue to assume that the lie detector can be as good as 90% valid on the average, even in this application. Does that then mean that we can expect to detect 90% of the liars and also that only 1 in 10 of those who "fail" the test are actually telling the truth? *It doesn't mean anything of the kind, not with these base rates.*

In what follows, I shall make use of the analysis presented in a classic paper by Meehl and Rosen (1955) which illuminates the relationship between the base rates of a condition (such as lying) in a population of persons to be tested, with the psychometric efficiency of the test that will be used to detect that condition (such as a lie detector). If the lie detector could produce an objective, numerical score, like a standardized aptitude or personality scale, then we might establish by preliminary research an optimum cutting score such that, if we called everyone scoring above the cut "liars," we would maximize the overall hit rate. Under such conditions, the best we could expect to do would be to identify 45 of the 50 liars in our group of 1,000 examinees. But, at the same time, 95 of the innocent truth tellers would also be expected to "fail," which means that $(95)/(45 + 95) = 68\%$ of the people who "fail" the test will actually be innocent!

However, even this rather forlorn result is better than we can actually hope to achieve in practice because in fact the lie detector does *not* yield an objective, numerical score. As in the Rorschach or the TAT, the examiner's brain is an integral part of the machinery of the test, and it would obviously be very difficult to train an examiner to set his subjective cutting score in such a way as to produce an optimum validity for a given base-rate situation. For the case under consideration, if he set his cutting score too low, "failing" 40% of the cases, for example, then the *best* he could do would be to "fail" all of the liars but at the cost of "failing" more than one third of the truth tellers, in which case 88% of those identified as "liars" would in fact be innocent. To properly train operators for this situation we would need the same nearly unobtainable facilities that we would need to make meaningful estimates of the actual validity of the lie detector in the employment screening situation, namely, an independent criterion which would tell us which few subjects were in fact lying. Since this is almost certainly impossible to achieve because validity estimates obtained from a very different situation with very different base rates are a most uncertain guide when one is working in this new situation, and since whatever validity one *can* achieve here will be at the cost of an extremely high proportion of false-positives—innocent subjects who "fail" the test and therefore lose their jobs or suffer other unwarranted consequences as a result—it seems plain to me that the use of the lie detector in this lucrative but highly dubious application should not be condoned.

Any professional polygrapher who may read these words will be gnashing his teeth at this point because these statistical arguments will seem to conflict sharply with his actual experience in this lie detector application. He will be thinking of all those shame-faced individuals who have been led to confess assorted peculations under the pressure of the lie detector examination. This undeniable ability of the polygraph to function as a sort of "painless third degree" was mentioned briefly earlier. If it were possible to make use only of these elicited confessions, discarding from further consideration all tests which did not produce such a result, then these questions of validity would be dealt with very differently. But, of course, once the population to be tested gets wind of the fact that no one is going to "fail" unless he confesses,

there are not likely to be any more valid confessions. A reasonable proportion of subjects will *have* to be "failed" on the basis of the test alone, and, under the circumstances I have been assuming, we must expect that most of those who "fail" in this way will actually be innocent.

The conclusion from all of this seems to me to be obvious and compelling. It is most unlikely that we shall ever have an objective lie detector procedure that can routinely claim as high as 90% validity; there is no reason whatever to imagine that any known lie detector, human or polygraphic, can achieve validities close to 100%. Lacking near-perfect validity, both of the previous considerations militate against the use of the lie detector *at all* in employment screening, that is, both the fact that decisions here tend to be based on the lie test alone and the fact that, with low base rates for lying, the majority of those who fail the test are going to be innocent. For this reason, I testified before the 1973 session of the Minnesota Legislature in support of a bill (Senate File 612) that specifically prohibits any employer from requiring or even requesting any employee or prospective employee to take a polygraph examination. The single exception authorized by this act is the use of the lie detector in the investigation by a police chief of possible malfeasance on the part of a police officer. I am happy to report that this bill was passed and is now the law in Minnesota.

Conclusion

The polygraphic interrogation industry is rapidly expanding and is already having considerable social impact. Polygraphic interrogation is a form of psychological testing; psychometric theory and psychophysiology are—or should be—its basic sciences. In fact, however, only a handful of psychologists know enough about the lie detection business to evaluate its claims and to provide expert testimony to courts and legislative bodies.

A polygraphic method known as the Guilty Knowledge Technique appears to have the potential for very high validity in the restricted number of criminal investigations where it is applicable. But the GKT seems to be unknown to professional polygraphers and there have been no studies either of its range of applicability or of its validity in field situations. It is certain that the GKT could not be usefully adapted to employee screening, the application which is currently providing the strong eco-

nomic impetus to growth of the polygraphy industry.

The techniques used by professional polygraphers can be appropriately characterized as methods of lie detection. Analysis of the assumptions underlying lie detection indicates that, while these methods might be expected to have significant validity (better, indeed, than many other commonly used psychological tests), the *a priori* probability is exceedingly small that the lie detector could be nearly as dependable as the professionals claim. Since these claims of 95%, 98%, and even 100% validity are so implausible, they should be taken seriously only if accompanied by unusually clear, well-replicated empirical evidence. Such evidence is wholly lacking.

In the preemployment screening situation, where the base rate for lying can be expected to be low, a high proportion—probably the majority—of those who "fail" the lie detector test will be false-positives. For example, if 5% of those tested are liars, then even with a test having 90% validity, fully 68% of those who "fail" will be innocent truth tellers. For this reason, and because in the employee screening application the lie test typically determines disposition of the case—if you fail the lie test, you do not get the job—widespread use of these methods in the private sector must inevitably work an unjust hardship on many innocent but autonomically reactive individuals. In certain sensitive occupations such as police work, where social considerations require attaching greater importance to false-negative than to false-positive predictions, the use of the lie detector as a selection device can be justified. The general use of the lie detector in employee screening cannot be justified, however, and psychologists have a professional responsibility to oppose this growing practice.

The use of polygraphic interrogation in criminal investigation is fundamentally different. Here the base rate for lying is undoubtedly higher, and, most important, the penalty imposed on the unlucky false-positive is less severe: One cannot be sent to prison for "failing" the lie test. Judicious use of the polygraph in the criminal investigation context not only can improve the efficiency of police work but could also serve as a bulwark to protect the innocent from false prosecution. It is argued that the apparent potential of the Guilty Knowledge Method should begin to be exploited in this application.

Scientific Awards Announcement

The Committee on Scientific Awards is accepting nominations for its award program. The Committee selects up to three persons as recipients of the Distinguished Scientific Contribution Award who, in its opinion, have made the most distinguished theoretical or empirical contributions to scientific psychology in recent years.

A new award, the Distinguished Contribution for Applications in Psychology, has been authorized by the Board of Directors and will be given for the third time this year. This is presented to an individual who, in the Committee's opinion, has engaged in a program of research which is systematic and applied in character.

The awards are subject to the following limitations: (a) members of the Committee, former recipients of the awards, the President and the President-elect of the APA shall be ineligible. (b) The Committee shall seek diversity in selecting recipients, avoiding as far as possible the selection of more than one person representing a specialized topic, a specific material, a given method, or a particular application.

Names and appropriate information which will guide the Committee on Scientific Awards in conducting an intensive career review and evaluation should be forwarded to Office of Scientific Affairs, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036. *Deadline for nominations is January 15, 1975.*

Learning Theory and Intelligence

W. K. ESTES *Rockefeller University*¹

All scientific measurements of intelligence that we have at present are measures of some product produced by the person or animal in question, or of the way in which some product is produced. A is rated as more intelligent than B because he produces a better product, essay written, answer found, choice made, completion supplied or the like, or produces an equally good product in a better way, more quickly, or by inference rather than by rote memory, or by more ingenious use of the material at hand. . . .

Psychologists would of course assume that differences in intelligence are due to differences histological or physiological, or both, and would expect these physical bases of intelligence to be measurable. . . . Even if one aimed at discovering the physiological basis of intellect and measuring it in physiological units, one would have to begin by measuring the intellectual products produced by it. For our only means of discovering physiological bases is search for the physiological factors which correspond to intellectual production [Thorndike, 1926, pp. 11-12].

Such was the status of this problem when Thorndike was writing *Measurement of Intelligence* nearly 50 years ago.

Thorndike was well aware that in measuring intelligence we do go further than sampling an individual's current performance in order to predict his potentialities for various types of tasks. To the extent that we can sample performance for different individuals following equal opportunities to learn, we also infer relative rates of gain in performance in the future. In fact,

an obvious hypothesis, often advanced, is that intellect is the ability to learn, and that our estimates of it are or should be estimates of ability to learn. To be able to learn harder things or to be able to learn the same things more quickly would then be the single basis of evaluation. . . . If greater ability to learn means in part ability to learn harder things, we have excluded the vague general valuation of certain products and ways of producing only to include it again. . . . If greater ability to learn means only the ability to learn more things or to learn the same things more quickly, we have a view that has certain advantages of clearness and approximate fitness to many facts. Even less than in the case of truth-getting [insight into reality], however, do our present actual instruments for measuring intelligence measure directly a person's ability to learn more things than another person can, or to learn the same things more quickly. . . . Much evidence will therefore be required before we can wisely replace our present multi-

farious empirical valuations by the formula that intellect is the ability to learn more things or to learn the same things more quickly [Thorndike, 1926, pp. 17-18].

It seems to me that the preceding paragraphs could almost as well have been written yesterday as several decades ago. Little has changed with respect either to the basic method of measuring intelligence by the sampling of performance or to our inability to improve on this procedure by more direct measurement of learning abilities.

One reason why the great amounts of effort expended on problems of intelligence and its measurement in the interim have produced so little change in basic conceptions may have to do with the fact that from the time of Binet, the primary criterion for measuring intellect has been success in predicting performance in school and other situations requiring intellectual effort. Long ago, efforts to increase the predictive power of intelligence tests began to run into sharply diminishing returns, and it now seems quite possible that we are near the maximum attainable, given the usual limitations on time and expense of testing.

Thus, in raising again the possibility of replacing the characterization of intelligence in terms of performance with a characterization in terms of learning processes, I am not motivated by any expectation that appreciable gains in predictive power could be achieved. One of the motivations for a reappraisal is almost purely intellectual, and, again, I find that I can improve but little on Thorndike:

¹ The substance of this article was included in an invited address presented at the meeting of the Toronto Psychological Association, February 1972, and at a symposium on intelligence held at the University of California, Los Angeles, June 1971.

Requests for reprints should be sent to William K. Estes, Rockefeller University, New York, New York 10021.

We have learned to think of intellect as the ability to succeed with intellectual tasks, and to measure it by making an inventory of a fair sampling from these tasks, arranging these in levels of intellectual difficulty, and observing how many the intellect in question succeeds with at each level. . . . Such a definition in terms of tasks accomplishable, and such a measurement in terms of the contents of a graded inventory is sound and useful, but is not entirely satisfying. One cherishes the hope that some simpler, more unitary fact exists as the cause of intellect and that variations in the magnitude of this fact may provide a single fundamental scale which will account for levels and range and surface. Moreover, one realizes the desirability of search for the physiological cause of intellect, regardless of whether that cause be single and simple or manifold and complex [Thorndike, 1926, p. 412].

Thorndike went on to offer a specific interpretation of intelligence in terms of the learning theory of his day:

The standard orthodox view of the surface nature of intellect has been that it is divided rather sharply into a lower half, mere connection-forming or the association of ideas, which acquires information and specialized habits of thinking; and a higher half characterized by abstraction, generalization, the perception and use of relations and the selection and control of habits in inference or reasoning, and ability to manage novel or original tasks. . . . The hypothesis which we present and shall defend admits the distinction in respect of surface behavior, but asserts that in their deeper nature the higher forms of intellectual operation are identical with mere association or connection forming, depending upon the same sort of physiological connections but requiring *many more of them*. By the same argument the person whose intellect is greater or higher or better than that of another person differs from him in the last analysis in having, not a new sort of physiological process, but simply a larger number of connections of the ordinary sort [Thorndike, 1926, pp. 414-415].

According to this conception, an individual's effective intelligence at any time was thought to be determined jointly by his original intellectual capacity, identified with the number of potential connections available in his brain, and by the number of connections actually formed as a result of training and experience.

Thorndike claimed "almost crucial" evidence for his hypothesis in a collection of correlational data from tests he believed to measure the higher abilities of relational thinking and abstraction (sentence completion, arithmetical problems, analogies) and tests believed to measure lower, "associative" abilities (vocabulary, numerical calculation, information tests). From the finding that intercorrelations of the higher tests among themselves, of the lower tests among themselves, and of the higher tests with the lower tests were all of the same order of magnitude, Thorndike concluded that both the associative and the higher abilities must have "in the main the same cause [p. 470]." And the common cause must lie at the associative level because

the lower, associative abilities can be found without the higher (as in the mentally deficient), but the higher abilities are never manifest in the absence of the associative abilities.

Thorndike's conclusion rests on an assumption that we shall find in the sequel to be open to serious question, namely, that one can find subtests of intelligence scales which are relatively pure measures of either the associative or the higher abilities. Nonetheless, the number-of-connections hypothesis has continued to represent for several generations of psychologists and educators the way in which learning theorists would interpret intelligence.

Because of its conceptual meagerness, the hypothesis has never aroused among psychologists much enthusiasm for following up this line of inquiry. Consequently, it remains essentially without a competitor—never a healthy state of affairs in any scientific discipline. It seems most timely, therefore, to ask what form would be taken by a similar effort today, utilizing the richer body of theory that has grown out of several decades of research on learning.

Beyond utilizing conceptual resources that were not available to earlier investigators, I propose to take a somewhat different basic orientation. Thorndike's approach was to look at the learning theory of his day in order to see what concepts or ideas embodied in it might serve to account for differences in intelligence. Like many other investigators in the psychometric tradition, Thorndike seems to have viewed intelligence as a trait or characteristic of the individual that sets the limits on his level of intellectual functioning. An interpretation of intelligence in terms of learning would, then, entail finding some theoretically meaningful quantity with which variations in intelligence might prove to be correlated; his choice, as we have seen, was the number of available associative connections.

In the course of a rather extensive review of the literature on learning theory and intelligence (Estes, 1970), I have come to think that a new effort toward establishing a more significant working relationship between the two research traditions should begin by turning the problem around. Rather than looking to learning or physiological theory for some correlate of intelligence, I should like to focus attention on intellectual activity itself. By bringing the concepts and methods of other disciplines to bear on the analysis of intellectual behavior we may come to understand how the conditions responsible for the development of its

constituent processes and the manner of their organization lead to variations in effectiveness of intellectual functioning.

Analyses of Test Behavior

THE DIGIT SPAN TEST

If this approach has appeal in principle, we need next to consider just what behaviors to analyze in order to be sure that the activity we are dealing with is closely related to that involved in measurement of intelligence. The simplest and most direct approach, it seems, is to begin with the specific behaviors involved in responding to items on intelligence tests.

The idea of relating performance on subtests of intelligence scales to various psychological categories or functions is by no means new. In his detailed analysis of the Stanford revision of the Binet scale, McNemar (1942) considered the idea that the various subtests of the Binet that seemed to have something to do with memory (e.g., digit span, repeating sentences, copying bead strings from memory) are alternative measures of a single memory function that might represent a purer manifestation of intelligence than the variegated tests of the scale as a whole. McNemar found the reliability of a pooled "memory" test to be relatively low and took this finding as rather negative evidence. However, he was not entirely satisfied with this basis for a conclusion and added:

The final answer as to whether variance in measured intelligence is more dependent upon retentivity than upon original learning, or as to the extent of each as a contributor, must be sought in the laboratory. We hazard to guess that securing the answer will involve experimentation rather than wholesale correlational analysis [McNemar, 1942, p. 151].

The experimental analysis that McNemar found so sorely wanting 30 years ago did not follow with unseemly speed. Consideration of the few examples of relevant research that are now available will, I think, make clear some of the reasons for the long delay in their appearance. I suggest that we will find a dominant factor to be changes in the state of theory concerning learning and memory over this period.

In order to give some idea of the kinds of analyses that are immediately within our reach, I would first like to discuss two cases in which the identical task that constitutes a subtest of an intelligence scale has been subjected to laboratory investigation, and then two cases in which only rather modest extrapolation from closely relevant research is required.

One of the simplest appearing subtests of the Stanford-Binet is the digit span test. As it occurs in the scales for Year 10, for example, the subject's task is to repeat a sequence of random digits immediately after they have been read aloud by the examiner. Successful recall of a string of six digits in the correct order is scored as passing performance at this level. The test correlates satisfactorily with total score on the Binet scale and with usual validation criteria, so it evidently samples some aspect or aspects of intellectual performance. But if an individual scores low on this test, what measures should we expect to be useful in improving his performance in this kind of task? An obvious possibility would be practice at recalling sequences of digits. But this seems rather narrow and most unlikely to transfer to any other situation. A better plan might be to have the individual practice recalling sequences of items of different types, digits, letters, words, etc.

These suggestions, together with an admonition to carry out the practice in a variety of contexts, would seem to be about all that could be derived from the learning theory available to Thorndike (1926) when he was writing *Measurement of Intelligence*.

If any subtest of the Stanford-Binet measures only the lower, associative abilities, the digit span test must surely qualify. The basis for successful performance would be conceived in classical association theory to be the establishment, or at least the strengthening, of interitem associations so that if, for example, the digit string 691472 were presented, the resulting structure in memory might be represented as 6-9-1-4-7-2. The request to recall would be the stimulus for remembering the first digit of the string, this in turn would lead to recall of the next digit and so on. If an individual failed the test, the interpretation would be either that he was inefficient in forming the required new associations, or that the strength of these associations in memory decayed too rapidly to permit successful recall.

A substantial body of research and theory dealing with short-term memory for sequences of items shows quite clearly that this interpretation in terms of interitem associations is inadequate and is in fact quite possibly entirely wrong.

Perhaps the most basic difficulty is presented by rather direct evidence that the item in position n of a string is not a necessary and sufficient stimulus, or even necessarily part of the stimulus, for recall of the item at position $n + 1$. For example, Jahnke (1970) showed that for most serial positions in a string, an individual's recall of the item at position n is better if he is simply asked to recall the item at that serial position than if he is given the item at position $n - 1$ and asked to recall its successor. This result was obtained with young adults who, it appears, must have established in long-term memory a conception of the sequence of ordinal numbers and must also have available a strategy of relating incoming items of a sequence to ordinal position.

There is considerable evidence to suggest that no effective associations at all may form between adjacent items in a sequence unless the individual has been instructed that he will be required to use individual items as retrieval cues in a subsequent test. Lesgold and Bower (1970) found no transfer whatever from learning of a serial list of items to a subsequent paired-associate task in which the pairs were adjacent items from the serial list unless the subjects had been informed in advance of the relationship between the serial and paired-associate tasks.

Numerous studies that have appeared since Miller's (1956) introduction of the concept of *chunking* have shown that, for strings greater than three or four items, recall is greatly facilitated if the individual groups the items into subgroups of approximately three items each. This procedure of grouping, or chunking, whether done by the experimenter as he presents the material or spontaneously by the subject as he attempts to organize it in his memory, is a powerful determiner of what is and is not learned in a short-term memory situation. Bower and Winzenz (1969), for example, showed that when the material is grouped by the experimenter at input, repetition of the string of digits leads to improvement in recall only if the particular mode of grouping is the same upon subsequent repetitions of the string.

Further, grouping is as important a factor with children as with adults, and with mentally deficient or brain-injured children as with normals. Spitz (1966), utilizing a modified digit span test with visual presentations, showed a substantial facilitatory effect of grouping of the digits upon performance of retarded children with an average IQ of 60;

the effect was present but smaller with equal mental age normals, perhaps because the grouping (by twos rather than by threes) was not optimal. Notably, it was found that when the retarded children who had been given the grouped presentation were subsequently tested with ungrouped material, their performance declined, whereas that of normal children was unaffected, indicating that the retarded children had not developed the habit of spontaneously grouping material in order to aid recall.

These and related lines of evidence have suggested an interpretation of short-term memory for strings of verbal units in terms of organization and coding. Johnson (1970) developed in detail the idea that grouping facilitates recall because the individual assigns a code to each subgroup of a sequence and maintains in memory only the smaller set of codes until the time of recall, when he decodes these in order to reconstruct the original sequence. When these ideas are taken into account, the simple schema of classical connectionism becomes amplified into a hierarchical structure of representations in memory:

LIST		
CHUNK 1		
Position 1	Position 2	Position 3
6	9	1
CHUNK 2		
Position 1	Position 2	Position 3
4	7	2

On presentation of the digit sequence 691472, the individual is conceived to subgroup the sequence into two chunks, assigning a code to each which he maintains in memory, and within each chunk relating the items of the sequence to the ordinal numbers 1, 2, and 3. On a request to recall the string, the individual brings into memory his coded representations of the two chunks; each of these in turn activates recall of the individual digits and their associated serial positions. While this process goes on, the individual must hold the partially reconstructed sequence in an output response buffer by an inhibitory process until the decoding is complete and then emit the digits in the proper order. This schema may seem complex, and certainly in details it is by no means beyond controversy, but numerous lines of solid evidence in addition to those reviewed briefly in the preceding paragraphs indicate that something not far from this theoretical picture is required (Estes, 1972).

With the revised schema in mind, we can readily see that there must be many different ways in which major individual differences can arise with respect to performance on a digit span test. In the young or the mentally retarded child, we may find failures occurring because the individual has not developed sufficient familiarity with the sequence of ordinal numbers, or enough experience in using the number sequence to order other materials. An individual of any age may fall short of standard performance if he has not developed the strategy of grouping to the extent characteristic of his age group, but may perform normally when led to utilize grouping by the experimenter or examiner. Another individual may not be able to accomplish the coding process necessary to take advantage of chunking even when material is presented to him in subgroups. Still another may be able to recall well enough but may lack the capacity for selective inhibition necessary to order his output properly.

Clearly it would be possible with the advantage of added theoretical insight to augment the standard digit span test in such a way as to localize the source of difficulty for an individual who fails under the standard procedure. This augmentation would quite likely do little to improve the predictive value of the test, but it might be of considerable help in indicating how deficient performance in this and related tasks might be remedied.

DIGIT SYMBOL SUBSTITUTION

Although various aspects of the digit span task have been studied in the laboratory, the fact that it also appears in intelligence scales is largely coincidental. Motivation and direction for these studies have arisen from previous theory and research on learning and memory. I have been able to find very few instances in which a task has been taken directly from an intelligence scale and subjected to experimental investigation with a view to elucidating the basis of its clinical usefulness. Of these, the most substantial is the recently reported investigation of the digit symbol task by Royer (1971).

The point of departure for Royer's study was the digit symbol subtest of the Wechsler Adult Intelligence Scale, which has been of special clinical interest because of its steep decrement in performance with age and its sensitivity to various neurological defects. In the standard form of the test, the individual being examined is given a table relating nine symbols to the digits 1-9, as illustrated in the

Digit symbol test

1	2	3	4	5	6	7	8	9
—	⊥	□	⊏	⊐	○	∧	×	=

8	1	5	9	7	2	8	4	3

1	2	3	4	5	6	7	8	9
⊏	⊐	⊥	⊏	⊐	⊥	⊏	⊐	+

Figure 1. Assignments of symbols to digits in Wechsler digit symbol scale (first two rows) and in set 5 of Royer's (1971) study (last two rows), together with sample from an answer sheet (third and fourth rows).

upper two rows of Figure 1, and an answer sheet with rows of boxes above which numerals appear in a haphazard order. His task is to place the appropriate symbols in the boxes, and his score is the number of substitutions completed in 90 seconds. The task can just as well be presented in reverse, with numerals being substituted for symbols, and in fact Royer studied both variations.

Royer (1971) noted that the test can be considered to be a measure of information-processing capacity because an index of rate of information processing derived from information theory proves to be linearly related to standardized score on the test. Further, within the set of symbols two types of information which have been significant in perceptual theory may be distinguished. One of these, which for brevity may be termed *spatial information*, serves only to distinguish members of a subset of symbols which belong to a rotational equivalence set, that is, which may be superposed following an appropriate rotation (e.g., the third and fifth figures in the second row of Figure 1). The other type of information distinguishes figures that cannot be superposed following any possible rotation.

In his first experiment Royer (1971) varied the distribution of digits on the answer form—balanced (rectangular) versus unbalanced—the latter being

the condition obtaining on the Wechsler scale, and relative proportion of content and spatial information in the symbol set. The symbol set from the Wechsler scale was utilized, together with four others which included increasing proportions of symbols that differed only on the spatial dimension. The fifth set, in which all but one of the symbols belonged to the same rotation-equivalence set, is shown in the bottom row of Figure 1. Administration of this set of variations to a large group of college student subjects yielded no significant effect of the distributional variable but a substantial and virtually linear function relating score to the similarity condition.

One might be tempted immediately to seize on this function as indicating the basis for clinical significance of the test because difficulties in handling the spatial information component are known to characterize young children and individuals with various neurological disorders. However, we should first examine the task more closely in order to see whether other aspects of performance might covary with the nature of the symbol set. At each step in the task the subject must inspect the next digit, go to the proper location in the table, code the information distinguishing the symbol found, and carry this information in short-term memory long enough to reproduce the symbol in the proper answer box.

Looking first at the purely motor aspects of the task, one must inquire whether one relevant factor might be differences in difficulty in reproducing the symbols in the various sets. Royer (1971) investigated this possibility in a second experiment in which subjects were required simply to copy haphazard sequences of symbols drawn from the various sets. He found a significant trend in the same direction as that obtained for test performance, but concluded that the variation was relatively small compared to that in the substitution task itself.

Probably of considerably more importance are factors having to do with the coding of the information in the symbols. Excluding individuals who can maintain fully adequate visual images, probably a rarity in the adult population, efficient performance must depend on the individual's having available or being able quickly to produce distinctive codes to represent each of the symbols in memory. On this assumption, the task would be the easiest for the Wechsler symbols. Many of these have distinctive labels readily available, for example, a minus sign for the first symbol, an in-

verted T for the second, and an L for the fourth (second row of Figure 1). In contrast, the symbols of Set 5 (bottom row of Figure 1) would require the creation of an adequate labeling system in the course of the substitution task.

Once accomplished, coding will obviate the necessity of looking more than once at the symbol required for a given substitution. Further, it is likely that even within the short time involved in the test some individuals will be able to learn some of the digit code associations and thus on many occasions not need to look from the digit to the table at all in order to make the appropriate substitution. It is clear from examining the sets of symbols used by Royer that suitable codes would be least readily available for the set containing the largest number of members of a single rotational equivalence group.

A satisfactory interpretation of Royer's principal results awaits further research which may serve to differentiate the role of relative proportions of content and spatial information from that of availability of distinctive codes. Evidence now available seems rather clearly to point to the latter interpretation. I have in mind, particularly, the extensive data concerning sex differences in performance on subtests of intelligence scales. Generally, girls score higher on verbal subtests, and boys, on those involving spatial manipulations. Digit symbol substitution has usually been assigned to the nonverbal category, and consequently the superior performance by girls (McNemar, 1942) has seemed an anomaly. The explanation, I suggest, is that skill in digit symbol substitution involves a verbal-encoding process as a major component.

VOCABULARY

The ubiquitous vocabulary test, appearing, for example, at all of the higher age levels in the Stanford-Binet, is similar to the digit span test both in the deceptively simple appearance of the task and in the substantial growth of relevant theory over the years in which the test has been used, but differs in the lack of directly relevant experimental analysis in the learning laboratory.

Considering how inextricably the vocabulary test has been bound up with the assessment of intelligence over nearly three quarters of a century, it seems remarkable how little is known as to just what aspects of intellectual performance are being measured. In particular, we are largely ignorant concerning the extent to which the test taps vocabu-

lary, in the sense of the stock of words an individual uses or can recognize, as distinguished from the processes involved in constructing a definition or an explanation of the meaning of a word.

Vocabulary tests have been validated extensively, but evidently always against other measures or criteria of intelligence, not against alternative measures of vocabulary. What might these other measures be? One, in particular, is suggested by recent studies of Howes (1971) on the direct estimation of an individual's vocabulary via time-sampling procedures. Howes' method is to record several thousand words of informal discourse from an individual, then, utilizing a statistical model relating word samples to populations, to obtain an estimate of the individual's vocabulary which is quite independent of the other processes involved in answering the usual vocabulary test items.

In terms of contemporary learning theory, what should we expect to be the principal determinants of performance when an individual is presented with a series of words and asked to give definitions or explain their meanings? Most basic, in a sense, must be the long-term memory structures established by previous experience with the words in question. In classical association theory, this result of past learning was conceived of simply as a set of associations between a particular word and others which might be used to convey its meaning. In contemporary thinking, the status of a word in memory is characterized by its values with respect to a set of features or attributes (Anglin, 1970; Underwood, 1969). Accessibility to this representation in memory is determined by the presence of retrieval cues (Tulving, 1968), which may be conceived as learned associations between the cluster of features and the contexts in which the word has

been or might be used. But the existence of these associations is not enough; actual performance at any time depends on their availability, which in turn is a function of recency and frequency of usage (Allen, Mahler, & Estes, 1969; Horowitz, Norman, & Day, 1966).

Depending on the specific retrieval strategies that he has learned to use and the availability of retrieval cues, an individual who is asked to give the meaning of a word on a vocabulary test may function at a number of levels, as illustrated in Figure 2. The most primitive answer in a sense, and the least efficient, is that of simply giving some other words which are aroused by association. This type of answer deserves, and in practice receives, only partial credit because it does not tap the organization of word meaning in memory. If the coded representation of the word in long-term memory is activated, the individual can attempt to produce an acceptable answer by recalling specific occurrences of the word and their circumstances, by recalling a dictionary definition or its equivalent, or by actually expressing the features and attributes that serve both to relate and to differentiate the word from others in his long-term memory system.

Finally, though by no means least important, production of an acceptable answer in this as in any other test situation requires that the individual have in mind a conception of the characteristics of an acceptable answer, in this instance of an acceptable definition or explanation of meaning of a word. For a child who has grown up in a more or less average home environment with numerous opportunities and occasions to inquire concerning the meanings of words and to have these explained to him by parents and siblings, this requirement is so automatically satisfied that it may tend to be taken for granted. Whenever he is able to achieve the necessary information, the child will be able to generate an acceptable answer by comparing his own partially formed utterances with the properties he knows from his own experience to characterize a satisfactory definition. A child who has not had these opportunities will lack the basis for corrective feedback of his production.

Clearly an individual's successful passing of a vocabulary test provides valuable information as to the extent to which the numerous prerequisites for successful performance have been simultaneously satisfied by his combination of inherent capacities and past experiences. But failure gives little diagnostic information, for it can come about in many

Figure 2. Levels of response to a request for definition of a word, all except the lowest requiring activation of a representation of the word in long-term memory (LTM).

qualitatively different ways. Inability to explain or define a word on request may occur because the necessary memory structure has never been established, because of a lack of retrieval cues for an intact memory structure, because words required to express the definition are at low availability owing to disuse, or because the individual lacks a general conception of the required solution to this type of problem and thus gives an answer which is meaningful within his own frame of reference but not within that of the examiner.

I think we must concede that, in comparison to digit span, present learning theory is not so clearly in a position to prescribe directly ways in which conventional tests of vocabulary might be augmented in order to provide more information concerning the different processes involved in test performance. However, it does appear that the line of analysis we have illustrated may go beyond the classical psychometric approach in generating specific kinds of research which might provide bases for remodeling the vocabulary test from a pure instrument for prediction of performance to one more useful in diagnoses of processes.

WORD NAMING

One's first impression of this task, a subtest of Year 10 of the Stanford-Binet scale, may well be that it scarcely seems to constitute an intellectual task at all. The individual is simply requested to name as many different words as he can in one minute, excluding counting or the use of sentences. Since, however, correlations of this subtest with total test score and with criteria are of the same order of magnitude as those for subtests with more obvious intellectual content, closer examination is evidently called for.

Consideration of the performance required of the individual immediately points to two of the processes intimately involved in the vocabulary and digit span tests, namely, the availability of words as responses and short-term memory, respectively. However, it appears that neither of these can be a major determinant of individual differences in performance. All but the most severely retarded individuals to whom this test might be given must have many more words in a relatively high state of availability than the 28 required as a passing score at Year 10. Short-term memory must be involved to some extent because the individual must keep track of the words he has already given in order to

avoid repetitions during output. However, the bulk of available evidence (see Belmont & Butterfield, 1969; Estes, 1970) indicates that rate of short-term forgetting does not vary substantially with either age or intelligence over a wide range.

A more central factor in the word-naming test is manifest if we note that it is in a sense a limiting case of the free verbal recall experiment, in which the subject is read a list of words and then asked immediately to recall as many as possible in any order. A very substantial amount of recent research shows clearly that performance in free recall is largely determined by the organization of an individual's long-term memory system and the way in which he makes use of this organization to guide performance in the testing situation. Data obtained by administration of free-recall tests to various populations show that amount recalled from a given list length increases systematically with age, education, and intelligence and that the tendency of the individual to organize his output in terms of clusters of meaningfully related words exhibits parallel trends. More importantly, the performance of young or mentally retarded subjects can be brought up to substantially higher levels if the individuals are led by the examiner to make use of meaningful categories in organizing their responses (for a review of this literature, see Estes, 1970).

A sharp distinction needs to be made between the extent to which an individual's memory is organized in terms of categories and the extent to which he utilizes these categories in retrieving material in a test situation. For example, on examination with the usual procedures, children belonging to a non-literate African community appeared substantially inferior to American schoolchildren of similar age in free recall (Cole, Gay, Glick, & Sharp, 1971), and it would be easy to dispose of this not particularly surprising finding as an example of the effects of cultural deprivation on the African children. By means of a painstaking series of researches involving close examination of the subjects' performance and of its relation to their cultural background, these investigators were able to show that when the African children were led by special techniques to respond in terms of meaningful categories their recall performance improved sharply to a level similar to that of American schoolchildren.

Mandler (1967) reviewed evidence suggesting that an individual's total vocabulary may be organized into a hierarchy of clusters of meaningfully related words in much the same fashion as the

Figure 3. Schemata for processes of word naming by chain association (upper portion) and by utilizing a categorical organization of memory (lower portion).

smaller sample of material presented in a free-recall experiment and that efficient performance in a word-naming test depends importantly on the extent to which the individual utilizes this organization. Both the time required to retrieve words and the demands on short-term memory are greatly reduced to the extent that one runs through a set of categories in an orderly fashion, enumerating as many as possible of the words belonging to each category in turn. In Figure 3, this strategy (lower panel) is contrasted with the less efficient one of chain association.

The data of Cole et al. (1971) indicate that the habit of retrieving material from long-term memory by means of categories depends strongly on amount of schooling, but when amount of schooling is held constant, retrieval is only slightly related to either age per se or other aspects of cultural background. There is clearly a pressing need for still more analytical research to determine just what aspects of school experience are responsible for developing this type of intellectual strategy.

Conceptions of Intelligence and Learning Ability: Concluding Remarks

Now, where do we stand at a theoretical level with respect to the interpretation of intelligence in terms of concepts of learning theory? First, referring back to our starting point, we might ask how, in the light of ensuing developments, we would now evaluate Thorndike's proposal that differences in intellect are manifestations of differences in the total number of available associative connections. Research and logical analyses within the framework of modern learning theory have certainly done nothing to dampen the skepticism that most of us doubtless felt concerning the plausibility of Thorndike's conjecture. In particular, Thorndike's correlational evidence is now seen to be distinctly less than cru-

cial, for our analyses yield no reason to believe that any of the tests he used provide pure measures of either associative or higher cognitive abilities. But, although subsequent events have not supported Thorndike's hypothesis, neither can they be said to have disproved it. What does become clear upon consideration of the complex interaction of biological and environmental events and processes over a prolonged period which are necessary for the development of effective intellectual behavior is that a model of the type Thorndike proposed is incapable of refutation by any methods now at hand or even foreseeable.

To be sure, some contemporary investigators, especially among those seeking to ameliorate mental deficiency by biochemical or psychopharmacological techniques, appear to operate on the tacit assumption that something akin to Thorndike's model is correct. Thus, one sees studies reported in which groups of intellectually deficient animals or children are subjected to new diets or new drugs and then tested to see whether their performance has improved relative to normals. But this strategy seems doomed to be as fruitless in the future as it has been in the past. For even if Thorndike's conjecture were correct, and if someone were to discover a drug that produced a substantial increase in the supply of available connections, the individual who was treated could not be expected to manifest any sudden increase in intellectual performance. The increased potentiality might be there, but a substantial program of reeducation and training would be required to make up for the deficiencies in past learning and to lay the groundwork for the organization of processes needed for efficient intellectual performance. I suggest that to have any rational basis for expectations of fruitful results, research directed toward the amelioration of intellectual deficiencies by physiological and chemical therapy must be conducted in close conjunction with the intensive application of the most sophisticated resources of learning theory to help trace the way through the no-man's-land between capacity and performance.

With regard to continuing theory construction, we can begin to see that theories of the form "differences in intelligence are manifestations of differences in x" or "differences between retardates and normals are produced by deficiencies in x" are the wrong kinds of theories to be trying to construct. The urgent need now is not for better means of classifying people with respect to intellectual func-

tioning and correlating these classifications with other variables, but for understanding what brings about specific kinds of competence and incompetence in intellectual activity.

An additional source of motivation for exploring the possibility of characterizing intelligence in terms of learning processes, going beyond the purely intellectual challenge, has to do with the changing mood of society. We are seeing increased resistance to the very conception of testing and measuring intelligence solely for purposes of prediction. If the trend that we see reflected daily not only in the newspapers but in the more erudite journals continues, we may find that not far in the future it will become impossible to measure intelligence, except in white, middle-class children, unless we can demonstrate some direct value to the individual being tested. This demand might be met if, for example, it came to be recognized (and in fact to be the case) that the primary purpose of intelligence testing had become that, not of predicting intellectual performance, but rather of indicating and guiding measures that can be taken to improve intellectual performance.

Little can be accomplished in this direction with present instruments for measuring intelligence because these operate primarily by sampling performance, and in every type of intellectual task any given level of performance can arise in many different ways. One's first thought may be that our present instruments for measuring intelligence need to be replaced by new ones better suited for diagnostic purposes. Aside from the perhaps transient problem that we have no specific idea at present how to proceed in this direction, we face the major difficulty that almost inevitably new tests of quite different design will be less valid predictors of intellectual performance than those now in use.

An alternative route involves not replacing or revising, but rather augmenting present methods of measuring intellect. The desired goal may be achieved if we can interpret the processes involved in test behavior in terms of concepts drawn from learning theory and utilize these interpretations as a basis for developing techniques to localize the sources of the deficits in performance revealed by test scores. This is not to imply that one should expect practical benefits to follow quickly and easily from laboratory analyses of test behavior. At the very least, it will be necessary to go on to the analysis of situations outside the laboratory which call for various types of intellectual activity. How-

ever, it does seem that research on intelligence within the framework proposed here might prove as fruitful for theory as that confined to the psychometric tradition and might lead to additional long-term social gains.

Applied Behavioral Analysis of Societal Problems

Population Change, A Case in Point

STEVEN M. ZIFFERBLATT *Stanford University*¹

CARROLL G. HENDRICKS *Stanford University*

We face problems that challenge our survival. Not only the quality of life but life itself is at stake. Whether or not we continue to inhabit this planet depends on our ability to find solutions to critical societal and ecological problems such as population control and pollution. Psychologists are becoming increasingly involved with seeking solutions to societal problems because the concerns people bring to psychologists are often traced to problems at a societal level.

The challenge at hand for behavioral science, more specifically psychology, is assisting people to behave in ways that will insure our survival. New strategies must be developed that change societal problems by changing human behaviors.

WHY PSYCHOLOGY?

Medical science and engineering are among those disciplines that humanity traditionally relies on for solutions. A substantial technology now exists; the difficulty lies in its implementation. A number of effective sanitation, birth control, nutrition, and antipollution devices and products now exist, yet their employment is somewhat unsystematic and thus ineffective. Quite often these problems relate to the behavior of people employing the technology. Scientific tools are used to create a physical technology. Similar scientific tools must be used in delivering, implementing, and maintaining the use of this technology. Developing an effective birth control device is one thing, but designing an environment ensuring its proper use is quite another.

The problem of designing environments to insure proper use of technology is far too critical to the world to remain unexamined by the tools of science. Psychologists are scientists skilled in dealing with the problems of behavior and behavior change. Societal problems are ultimately problems in changing human behavior.

A PROBLEM OF PROBLEM DEFINITION

Approaches to societal problems in the past have proved so inadequate that even politicians are careful to talk of solutions in only the vaguest terms. A major obstacle is that problems are conceptualized in ways that do not facilitate solutions. What is done about a problem depends on how it is defined. The way a societal problem is defined determines the focus, the techniques of intervention, and the criteria for evaluation. The way a problem is defined also determines not only what is done about it but what is not done about it (Caplan & Nelson, 1973). If attitudes and values are argued to be the basis for problem definition in population change and family planning (Cordero, 1968), then a host of everyday behaviors and their motivational factors also quite close to the problem are possibly overlooked as the foci of change.

Social critics often provide perceptive analyses, but their criticisms are usually at a global, descriptive level. An analogue may be found in traditional diagnostic procedures in psychotherapy, in which a client is classified with a global label such as *schizophrenic* on the basis of diagnostic tests that have limited validity and reliability (Mischel, 1968; Stuart, 1970). The major criticism of these diagnostic procedures is that the label contributes little toward solving the client's problems. Similarly, current diagnoses of societal problems ("impending

crisis," "overpopulation," "lack of motivation") do not readily point to solutions (Ehrlich, 1970; Slater, 1969; Toffler, 1970). For example, Toffler summarized the major emphasis in his book as "diagnosis":

Yet the basic thrust of this book is diagnosis. For diagnosis precedes cure, and we cannot begin to help ourselves until we become sensitively conscious of the problem.

These pages will have served their purpose if, in some measure, they help create the consciousness needed by man to undertake the control of change, the guidance of his evolution. For, by making use of change to channel change, we cannot only spare ourselves the trauma of future shock, we can reach out and humanize distant tomorrows [p. 430].

What Toffler and others have not emphasized is *how* we are to promote critically needed behavior change. Scientifically based methods of behavior change exist, *but* we must learn how to use them.

Family Planning and Population Change: A Case in Point

A common thread weaving its way through psychological research in population change and family planning is the search for underlying and common causal variables that transcend individual differences within a culture and account for the problem phenomena (Carlaw, 1971; Cordero, 1968; Fischer, 1972; Rosario, 1971). Once these variables are identified through correlational and factorial research then hypotheses may be established and experimental research conducted. Finally, these hypotheses will hopefully lead to useful treatment strategies that eventuate in behavior change. When behavior change or control over behaviors related to problem areas are used as criteria, these attempts have not borne fruit. Studies have also revealed the prevalence of certain attitudes or values across a given subculture. However, it is one thing to reveal a value across a given subculture, but it is quite another to design intervention or change strategies for the same subculture. For example, psychoanalytically oriented psychologists maintain that the dynamics of childbearing, sexual drives, and generational continuity are a function of early childhood wishes (Benedek, 1952; Erickson, 1964; Kestenberg, 1968; Wyatt, 1967). Even if the validity of this information is accepted, the usefulness of this information, in relation to how it bears on changing the problem situation, is questionable.

Many attitudinal studies across cultures have appeared in the area of family planning and popula-

tion change. These studies relate to (a) child-bearing motivations; (b) parental attitudes toward existing children; (c) intelligence as a function of family size and child rearing; (d) population attitudes of students; and (e) individual meanings of sex, marriage, contraception, menstruation, and children (Fawcett, 1969).

Substantive findings leading to the development of change strategies that resolve the problem rarely emerge as consequences of these research activities.

One reason for the lack of action-oriented findings is the "state of behavioral science technology." Fawcett (1969) stated that "most attitude research in the population field is lacking in methodological sophistication." Others argue that there is a need for improved measurement of psychological variables in population studies (Radel, 1972; Stephens, 1962). Other social scientists have called for improved research designs; better statistical control over sociocultural factors and personal variables; better inventory or baseline studies; and better generation, testing, and evaluation of hypotheses (Bogue, 1966; Yaukey, Griffiths, & Roberts, 1967). These responses, which cite the lack of relevant and useful procedures to solve family planning and population change problems, are perhaps problems inherent in all psychological research. Typically, psychological research in these areas abounds with calls for "new role definitions," "better measurement procedures," "more sophisticated experimentation," or "a theory of family planning and population change."

These practices reflect a rather limited view of psychological research—that of hypothetico-deductive and nomological inquiry—a view that is currently accepted by psychologists in the area of family planning and population change. Nomological inquiry, simply stated, is based indirectly or directly on theory building—a search for relevant hypotheses, common factors, and causal variables ("building blocks") with the hope of eventually "putting it all together." However, the potential usefulness of this approach to understanding human behavior, as of this moment, is questionable. Elaborate theories of human behavior all stand side by side, all taught and researched, yet few create procedures able to change human behavior in beneficial ways. Population psychologists seem to be moving toward the reinvention of the square wheel. It is a luxury we cannot afford.

There are, in addition, certain "socialization" variables that psychologists doing this "scientific

and theoretically sophisticated" research are subject to and tend perhaps to maintain irrelevant behavior. Caplan (1973) noted that rarely, if ever, are advancement and recognition judged on the effects of one's scientific behavior on the people or problematic phenomena studies. What is good for the social sciences and the individual social scientist may not entail that it be good for those on whom research is being done.

Recently, in an American Psychological Association survey of 368 faculty members at 95 universities, 83% of the faculty members thought academic psychology should be concerned with solving social problems and 79% said it was making no significant contribution. Among 2,140 graduate students, 90% said psychology was not doing much to solve social problems. Both faculty members and graduate students cited unequal opportunities for education, poor race relations, deterioration of the environment, militarism, war, and poverty as issues psychology should be dealing with (Lipsey, 1973).

The point of this cursory review is to identify an epistemological bias in current psychological research in family planning and population change that contributes to its lack of relevance in providing solutions to problems.

There are empirically and technologically based alternatives available that are not as epistemologically eloquent, but perhaps are more to the point: changing people's behavior in ways that may provide solutions to family planning and population change problems.

In short, population psychologists simply must get on with the business of effecting changes in problem behaviors. Building theories or identifying variables that have little implication for altering problem situations is a luxury we cannot afford. Variables that explain or are considered causal may be the least alterable. For example, we do know that under certain conditions urbanization causes population explosions in minority groups. Yet the population psychologist or the applied demographer can do little to reduce the birthrate by manipulating "degrees of urbanization." Research into the relationship between urbanization and population growth has little immediate payoff in solving the problem. But psychologists can find ways to facilitate and promote behaviors related to contraceptive use, decision making, and modes of sexual activity. We are faced with societal problems that require solutions in fact, not in principle. The primary

questions are, What works? On whom? Under what conditions? *Why* things work is a long-term ambitious goal and one that may not enhance our chances for survival.

Family Planning Programs: The Current Status of Intervention Strategies

A number of ad hoc empirically oriented family planning programs have, in fact, been instituted. These programs emphasize (a) provision of supplies and services, (b) the dissemination of information, and (c) the education or training of health care agents (Bogue, 1966; Lozare, 1972; Ludhiana, 1963; Puerto Rico, 1963; Taichung, 1963; Worrall, 1971). Currently, major emphasis in family planning programs is placed on dissemination of information, supplies, or services. These variables are considered the major factors to be manipulated. Some programs have experienced moderate success with those families already expressing an interest in family planning (Ross, Germain, Forrest, & Van Ginneken, 1972). These programs do not extend to the vast majority of families who, for many reasons, do not receive family planning services.

Empirical evidence suggests that motivational factors might play a significant role in increasing the effectiveness of family planning programs (Ridker & Muscat, 1973). A number of alternatives have been suggested, for example, educational subsidies for children; old age security; employment opportunities; financial, material incentives; persuasion by significant people; and sundry educational programs. These alternatives possess a number of common attributes:

1. It is assumed that substantial impact can be made in family planning by providing more positive consequences (incentives or motivation) for a target population, for example, nonfertility, menstruation, or menstrual aspiration.
2. It is assumed that economic factors have great impact on motivators in a given culture.
3. Systematic efforts should be concentrated in a search for incentives. If appropriate incentives are identified and programmed, then changes will occur in family planning behavior.

What seems to be lacking from many family planning programs is (a) a clear statement of behavioral goals for a given family or program, (b) a methodology for focusing on those factors and behaviors that will most likely have an effect on the

problem behavior of a given family, (c) a procedure for selecting an appropriate intervention (change) strategy for a given behavior, and (d) a strategy that can represent *immediate* behavioral outcomes and lead to subsequent modification of a particular program.

IS FAMILY PLANNING A RATIONAL PROCESS?

One criticism of family planning endeavors is that family planning is not a rational process. This is, in part, due to the complexity of behavior; for example, there are a host of variables that might account for a family's decision to have or not to have children. "Rational" behavior usually suggests isolation of critical problem parameters and an ability to predict family planning behavior via the manipulation of those parameters. Thus, rationality of a behavior, simple or complex, is largely determined by our ability to perform a functional analysis of those events antecedent and consequent to the behavior under investigation.

Part of the problem may be that there are a number of conceptual orientations to problems available to behavior scientists. Each alternative, for epistemological reasons, arbitrarily includes and excludes various data, levels of data (behavioral, mental, historical, subconscious), and methodologies (nomological, inductive, comparative group, $N = 1$).

Problems that seem insoluble or extremely complex in one discipline or epistemological context may, in fact, be defined in different ways in another context and be subject to an alternative empirical approach. Let us take, for example, the problem of another complex set of behaviors: autism. We will trace its definition, its treatment, and finally its pessimistic prognosis within a medical model context and contrast this to recent developments in an alternative model for treating autism, a behavioral model. Recent developments with this latter alternative suggest that autistic behavior may be subject to a functional analysis.

Until quite recently, the predominant approach to the understanding and treatment of autism and other severe childhood disorders has been the *medical model*, which has included both psychodynamic (psychogenic) and biogenic schools. (Rimland, 1969; Rutter & Bartak, 1971; Rutter, Bartak, & Newman, 1973). The medical model is characterized by two assumptions or working hypotheses concerning the etiology and treatment of autism. The locus or cause of the disorder is internal. The

child's behavior is merely symptomatic of a variety of inner events (cognitive, structural, inherited, or metabolic). Another hallmark assumption of the medical model has been that therapy is derived from and consistent with notions of causation. This orientation has, in fact, been used in treating illness for several millennia. It is one of many alternatives, and in the case of autism the most optimistic interpretation of the results has been that they are "ambiguous." Many writers have noted that existing theories of autism are as yet unverified if not actually disconfirmed. Both the psychogenic and biogenic approaches to autism have been criticized for not providing confirming evidence of the essential internal emotional disturbance (Rutter, 1969) or of a physiological one (Rutter & Bartak, 1971).

In sharp contrast to the medical model is the *applied behavior analysis model*. The child's disordered behavior is the problem. No inference to personality, history, or unobservable or internal emotional conflicts is made. Instead the events that either generate or maintain the behavior are to be found in the child's immediate environment, particularly those events that impinge on the child in systematic ways, that is, certain classes of reinforcers that maintain inappropriate behavior. In other words, the child's problem is regarded as a direct consequence of here-and-now external stimulus events.

The contrast in these two models is indeed dramatic and exemplifies the point that statements concerning complexity and rationality are a function of epistemological bias. Until recently the most predominant model for autism was medical, along with its attendant epistemological consequences. Searches for underlying causal variables were the mainstream of research activity. Progress was slow. Autism was an untreatable mystery. Theories and rich in-depth euphemisms were abundant. However, when an alternative model was employed, namely, that characteristic of applied behavior analysis, the problem definition, locus, and methodology changed dramatically, and "complexity" became a useless descriptive variable. A search for a cause was laid aside, preceded by emphasis on solving the problem rather than explaining the problem. A technology was developed that provided a number of rapid and dramatic changes in the autistic child's behavior (Ayllon & Michael, 1959; Ferster & DeMyer, 1961; Lindsley, 1956). True, a causal framework has not been developed,

but a technology to treat the problem and change behavior has. An alternative framework has led to a radically different approach to problem solving, one that appears more parsimonious and practical. Its heuristic value and ultimate contribution to a causal explanation of autism might be limited, but, at the risk of being trite, it works!

The potential gains possibly obtained from an applied behavior analysis strategy to family planning problems, aside from its theoretical irrelevance, cannot be overlooked. An applied behavior analysis strategy identifies an array of problem parameters that are quite different from those derived from more medically and nomologically based inquiry models. For example, possible parameters might relate to the types of consequences that maintain very specific problem-related behaviors (social approval, status, extrinsic nonrelated material rewards, peer recognition, etc.). The schedule for their delivery (daily, immediately, hourly), their amount, or intensity might be another set of parameters, and other parameters might relate to controlling situations or discriminative stimuli which set the occasion for appropriate and inappropriate behavior (time, pre-intercourse procedures, meals, pill ingestion, and setting). Thus, what appears to be valued as irrational behavior might merely be a function of its epistemological context, as with autism. When viewed through alternative frameworks and accompanied by a different array of data and methodologies, family planning behavior might be quite rational.

Applied Behavior Analysis: An Existing Technology

A powerful technology for changing human behavior has emerged during the past two decades. Known variously as behavior modification or applied behavior analysis, this technology has been applied successfully to problems in education, psychotherapy, and institutional care (Thoresen, 1973). One reason for this success has been the techniques or behavior change principles that are part of applied behavior analysis. The systematic use of reinforcement, punishment, and modeling can account for substantial changes in behavior. But beyond technique, the success of applied behavior analysis is due in large part to the sequence of activities in which applied behavior analysts engage in order to solve problems. These activities, termed here as the *behavior analysis process*, may be ap-

plied to any problem, be it organizational, clinical, or personal.

Although there is considerable room for argument as to the exact range of these activities, most behavior analysts would agree that the following components are common to most, if not all, successful applications of applied behavior analysis.

BEHAVIORAL OBJECTIVES

An initial step in applied behavior analysis is the specification of objectives. Objectives in family planning have often been too vague to be meaningful. For example, an objective "to promote positive attitudes toward small families among Mexican-Americans in the Los Angeles area" does not specify a behavior, the extent or amount of the behavior required, or the conditions under which it should occur. In contrast, the objectives "to take one oral contraceptive pill every morning before breakfast" or "to visit the family planning clinic on the first Tuesday of the month at 10:00 a.m." specify the behavior, the amount, and the conditions. Proper specification of objectives in family planning can be extremely beneficial because the problem, in order to be solved, must be conceptualized as behaviors to be changed.

FUNCTIONAL ANALYSIS

An integral part of applied behavior analysis is a procedure called *functional analysis*, in which behavior is analyzed in the context of its antecedents and consequences. This procedure is often used as a diagnostic tool in applied behavior analysis programs because contingency relationships are often revealed through the observation of antecedent and consequent events. For example, antecedent events for taking a pill might be (a) a reminder, (b) a chart, or (c) the bottle placed on the breakfast table. Consequences might be social reinforcement in the form of a spouse or sibling compliment or a prearranged incentive for the behavior. Functional analysis, so named because behavior is a function of its antecedents and consequences, provides information about the events that control behavior and, therefore, about the events that must be changed to effect a change in behavior. Antecedents and consequences to "taking one oral contraceptive every morning at breakfast" control the behavior. The critical antecedent in a change strategy might be the system of cues a woman uses to remind herself to take the pill. Engineering such an environment

would set the occasion for the behavior. A meaningful consequence, in addition to the obvious one of remaining nonpregnant, might be a kind word from her husband. This would help to maintain the behavior.

BEHAVIORAL DATA

It has been said that the most important contribution of behavior modification has been in the use of behavioral data collected in naturalistic settings (Bijou, Peterson, & Ault, 1968; Johnson & Bolstad, 1973). The process of applied behavior analysis relies on information about the actions of human beings in the situations in which those actions are most relevant. An emphasis on what people *do* might be the most important step for family planners to take at present. For example, if a set of parents produces seven children, it might be inferred that their attitude toward birth control is at best *laissez-faire*. *All too often the attitude has been the data.* It would be more meaningful to collect information about the nature of the action that resulted in an unplanned conception by isolating a behavior and studying its antecedent/consequent events.

Although some behaviors in family planning must be started "from scratch," most of these behaviors are already extant in the repertoires of individuals. For example, everyone has pill-taking behavior in his repertoire, but this behavior must be brought under the proper stimulus conditions. Each family follows certain rituals antecedent to intercourse; these activities, with the addition of some birth control steps, can also be brought under the appropriate stimulus conditions.

PRINCIPLES OF BEHAVIOR

It is impossible to comprehend human behavior without considering the observable environmental, physical, social, and cultural events in which behavior occurs. These events, which precede or succeed behaviors, must be considered carefully in attempts to either change or initiate new behavior. Applied behavior analysis tries to identify these events antecedent and consequent to behavior and to "rearrange" the environment to obtain desired outcomes. This "rearrangement" entails deliberate and careful selection of potentially effective antecedents and consequences to influence the occurrence of more adaptive behavior. Principles of behavior such as reinforcement, extinction, cuing, and punish-

ment are, in fact, different combinations of pleasant and aversive antecedents and consequences. Their application in the form of contingency arrangements obtains desired behavioral effects, for example, acquiring, eliminating, increasing, decreasing, or maintaining behavior. Techniques such as behavior shaping, behavior contracting, modeling, and behavioral self-management help the scientist to apply principles of behavior (Thoresen, 1973).

Thus the specification of objectives and data in behavioral terms provides observable and measurable units of behavior, and a functional analysis points toward the factors that govern behavior. Finally, the actual application of one of the principles of behavior change, such as reinforcement, shaping, cuing, or extinction, is indicated by the feedback of information gathered through the following sequence of activities in the behavior analysis and change process:

1. State the problem in behavioral terms.
2. Perform functional analysis of problem-related behaviors (incorporate interdisciplinary contributions).
3. Designate target behavior.
4. Formulate behavioral objectives.
5. Develop an intervention strategy (apply principles of behavior).
6. Implement the intervention strategy.
7. Evaluate (compare data with behavioral objectives).

The Interdisciplinary Contribution to Societal Problem Solutions

The effectiveness of applied behavior analysis depends largely on identifying relevant behaviors and events for observation. Applied behavior analysis can provide the operational and procedural aspects of behavior change. Yet a universe of observational data exists for each human being and the problem-related behavior. Systematic and knowledgeable guidance is required to isolate critical behaviors and events in the culturally unique environment of each individual. Different cultures, for instance, provide differential male sex roles and incentives (e.g., money versus status), religious practices, and social behaviors which may lead the scientist to observe and select different contingency arrangements in developing an intervention strategy for population change. We may, for example, learn that there are different economic and social antecedents and consequences for large families in rural,

as opposed to urban, settings. Descriptive and empirical data from the disciplines of anthropology, psychology, and sociology can help to focus observations and analysis on relevant behaviors and events (Bijou et al., 1968).

Knowledge largely derived from marketing and advertising disciplines may provide techniques that enhance the delivery and acquisition of behavior in an intervention strategy. Thus, techniques relating to (a) personal influence channels, (b) media selection, (c) message structure, and (d) promotion may be useful adjuncts to tools derived in the social sciences (Lieberman, Gillespie, & Loghman, 1973; Worrall, 1971).

Behaviors related to societal problems and their solutions are embedded in a larger social systems context; that is, behavior change of patients and clients depends on the behavior of change agents such as public health officials, counselors, and nurses. Social systems theory (Berrien, 1968) and systems design and analysis (Zifferblatt, 1972) lend both a conceptual and operational framework to the maintenance of the change agent's behavior and thus the client's behavior. Recent investigations in the field of education indicate that generating behavior change is largely a function of developing effective change programs for the agents of change, as well as for the target population (Bushnell & Rappaport, 1971). The generation and maintenance of these supportive behaviors are equally subject to the principles and techniques of applied behavior analysis. Thus, applied behavior analysis can provide operational procedural contexts for the contributions of other disciplines (Zifferblatt, 1973).

Applied behavior analysis, in conjunction with technology, can provide the powerful tools needed to deal with critical societal problems. The challenge to psychology is clear. An effective behavior change methodology must be employed to address the most serious crisis yet to face mankind.

The Intensive Design: A Methodology for Analyzing Intervention Programs

Most analysis and evaluation models employed in intervention programs have been what Kaufman (1972) termed "summative," designed to determine if there are significant terminal differences between treatment and control groups. Various factorial designs are used to compare completed treatment programs with numerous subjects assigned to a

variety of treatments. The supposed advantages of these designs are well known. Statistical techniques allow the experimenter to calculate the probability that results were due to chance rather than to treatment effects; multiplicity of cells, each with a large N , allows for greater generalizability; controls are placed on unwanted sources of variability. Great emphasis is placed on generalizability of results and ascertaining the degree of causality of particular problem-related variables. There are, however, some severe limitations to this model when emphasis is not placed on causal and generalizability criteria, but on achievement of results (behavior change) with a given individual. As discussed previously, problems of family planning and population change are a function of many idiosyncratic behaviors and events in a culture. Changing the behavior of individuals concerned with the problem requires careful selection of variables from the many possible sources of the problem. The goal is purely a technological or practical one: solving the problem, rather than developing a generalizable unilateral theory or explanation of the problem. Traditional analysis and evaluation models are typically concerned with group (generalizable) trends. It is quite possible that in a large group study, a statistically significant effect may be demonstrated when in fact the variable or treatment suggested is clinically senseless. While the effects are statistically generalizable, they do not enable prediction of how any particular subject would respond.

In a results-oriented context we are concerned with individuals achieving criteria and how this might be accomplished. To illustrate, in a results-oriented program we are concerned with whether or not an individual is engaging in birth control behaviors. If the desired result fails to occur, a different technique may be employed and so on until the desired effect does occur. Clearly, an individually and practically oriented analysis model is needed to progress systematically toward practical problem solutions. Applied behavior analysis, as the term connotes, characterizes such a methodology.

Thus, applied behavior analysis offers the following advantages for the family planning psychologist interested in actually changing the behavior of individuals (Thoresen, 1972):

1. The specific actions of the individual subject are the unit of focus, rather than comparisons between groups of individuals.

2. The frequency and magnitude of an individual's behavior can be examined continuously during all phases of the investigation.

3. The individual subject serves as his own control in that behaviors resulting from intervention are compared with his own baseline before intervention.

4. Control of variables related to the problem is facilitated by immediate and ongoing feedback of the individual's performance.

5. The clinician can determine immediately the extent of relevant changes continuously during treatment and other treatment if necessary, based on the data provided. The clinician is able to continuously alter treatment conditions as he strives to obtain criteria.

6. Typically, applied behavior analysis observation and analysis are employed in the settings in which the behaviors naturally occur. All data gathered are thus based on naturalistic conditions.

Applied behavior analysis methodology is particularly suited to results-oriented intervention. A basic observation and analysis procedure is employed to identify (a) problem behaviors, (b) appropriate behaviors, and (c) significant events that precede and follow these behaviors and tend to maintain them. After a behavior is targeted for change, the environment is rearranged to bring about this change. Data are kept continuously on the occurrence of the behavior. Any change that occurs is immediately observable. If no change occurs, then a new arrangement is designed. This process is repeated until the outcome criterion is attained.

Thus, applied behavior analysis strategies are designed to facilitate outcomes rather than to provide generalizable knowledge. Generalizability is usually obtained through controlled series of replications (Sidman, 1960).

Family Planning = Behavior Change

Family planning behavior change, in any culture, is individual behavior change. Procedures such as health education, accessibility, and exposure to information are simply not powerful enough to change behavior. If these procedures were effective, there would not be so much concern over the relative inefficacy of current preventive health programs. While "behavior change" and "education" seem to

be redundant terms, the latter is notoriously lacking in operational attributes.

Each family brings to the family planning specialist a singular repertoire of rituals, interactional idiosyncrasies, individual family arrangements, and specific behavioral assets and liabilities that provide little justification for unilateral action, for example, different social skills, different scheduling habits, different responses to spouse criticism, different home spatial arrangements, and different significant people. While it is important to recognize the possible impact that incentives or motivators might have on family planning, in general it is more important now to identify what events from an array of incentives or motivators and what specific behavior in a given family should be focused on. Both the family planning counselor and the family should participate in this decision, thus increasing chances for success. A systematic methodology is available (a) for identifying behaviors and variables that might be brought to bear on them, (b) for altering the specified behavior in an appropriate direction, and (c) for evaluating program outcomes.

Applied Behavior Analysis and Family Planning Programs: A Suggested Direction

In this section of the article, two suggestions will emerge for the application of applied behavior analysis strategies to family planning and population change: (a) the development of a training program and materials for family planning or health workers and (b) the development of a taxonomy of relevant behaviors and contingency arrangements for a given culture and a taxonomy of behavior requisites for all existing birth control devices.

Family planning programs in newly developing countries are usually implemented by medically trained personnel at various levels. Training is typically in medical information about the various birth control devices, communication modalities, and health education. Indonesia's program, for example, employs mass motivation programs, family counseling, information dissemination, a speakers' bureau, entertainment, and family planning education as training components (Winslow, 1972).

This multifaceted approach to the problem of population change may be considered characteristic of other programs in India, Taiwan, Costa Rica, Pakistan, and the Philippines (Lozare, 1972; Ross et al., 1972; Stienborg, 1970; Wake Forest, 1971).

The effects of a behavior change technology have been demonstrated on a variety of behaviors related to health, social, and educational situations in several thousand empirically based studies (cf. Bandura, 1969; Franks, 1969; Katz & Klutnick, in press). Negative thoughts, hitting, tantrums, managing blood glucose levels, cigarette smoking, cardiac anxiety, obesity, and pill taking have been operationalized as behaviors that are subject to analysis and change. In addition, applied behavior analysis strategies have repeatedly demonstrated effectiveness in identifying, analyzing, and solving problems in families (Brown, 1972) by deliberate installation of new adaptive responses or by changing motivational factors (contingency arrangements).

Most relevant is the point that the technology demands no special theory or extensive training skills. Appropriate levels of skills can be acquired relatively quickly. A review of training applications of applied behavior analysis skills reveals successful training and application by parents, children, neighbors, nurses, physicians, and grandparents (Guerney, 1969).

Applied Behavior Analysis and Cultural Contexts

Furthermore, applied behavior analysis procedures are designed to analyze behaviors in their natural context, so these processes are generally culture free. Applied behavior analysis is a set of procedures, not a set of theories. Rather than imposing a set of theoretical biases on a given culture (e.g., interpreting Malaysian fertility procedures via Freudian theory), applied behavior analysis provides means for the analysis of the unique variables that control behavior across cultures. For example, a set of rural Malaysian parents may not practice any means of birth control, and this behavior may be maintained by certain covert reinforcing consequences. A large family may be functional in that culture by providing social and economic comfort for the parents in their declining years. A set of rural Canadian parents may not practice birth control, and this behavior may be maintained by an entirely different set of reinforcing consequences. A large family may be functional in the latter culture by providing immediate labor for the family's farm.

The antecedents or substantive events that set the occasion for intercourse may vary in different cultures and also lead us to an understanding of the problem behavior and how it might be altered. For example, in Malaysia where families may live together in one room, spontaneous intercourse (capitalizing on privacy) might be a powerful event antecedent to intercourse. In rural Canada the intemperate climate may generate certain affiliative social behaviors leading directly to intercourse during highly predictable time segments (the cliché about "long winter nights" might be appropriate here). Both overt and covert events and behaviors are part of the functional analysis of problem behaviors. The exact idiosyncratic event or behavior may vary from culture to culture, but the process of ascertaining them is quite the same. In each case such a problem analysis would suggest which events—antecedents or consequences—might be altered to produce changes in behavior.

Suggested Training Program Objectives

1. To develop an empirically based, outcome-oriented prototype model for delivering and maintaining family planning programs.
2. To train existing personnel in family planning and health in skills that will enable them to develop their own family planning or training programs.
3. To provide families with the opportunity to (a) generate empirical data on family planning, (b) participate in the decision-making process with the family planning worker, and (c) experience a greater degree of satisfaction and long-term gains from the family planning experience.
4. To provide a model for defining a societal problem that enables many personnel to participate in its solution.
5. To develop a set of training procedures, manuals, and materials relevant to the varied needs of a newly developing country, in the areas of basic behavioral analysis and change skills.

Training objectives can be designed for (a) trainers of family planning workers, (b) family workers, and (c) the consumer.

Suggested Training Objectives for Family Planning and Health Workers

1. Observation of behavior related to family planning problem:

- 1.1 Application of behavior observation skills;
- 1.2 Use of behavior observation forms;
- 1.3 Training families to observe their own behavior;
- 1.4 Identification of problem-related behavior and behavior required to solve problem.
2. Environmental analysis of problem-related behaviors:
 - 2.1 Identification of antecedents and consequences available for (a) the behavior to be changed and (b) the new behavior targeted;
 - 2.2 Selection of consequences and occasions (motivating environment) for the targeted behavior;
 - 2.3 Formulation of behavioral objectives for the family.
3. Application of behavior change strategies:
 - 3.1 Selection of appropriate change strategy: reinforcement, shaping, contracting, extinction, cuing, modeling, self-change.
4. Collect data.
5. Evaluate outcomes and modify program until behavioral objectives are achieved.

Prerequisites to the Application of Applied Behavior: A Behavioral Taxonomy of the Culture and of Applicable Birth Control Devices

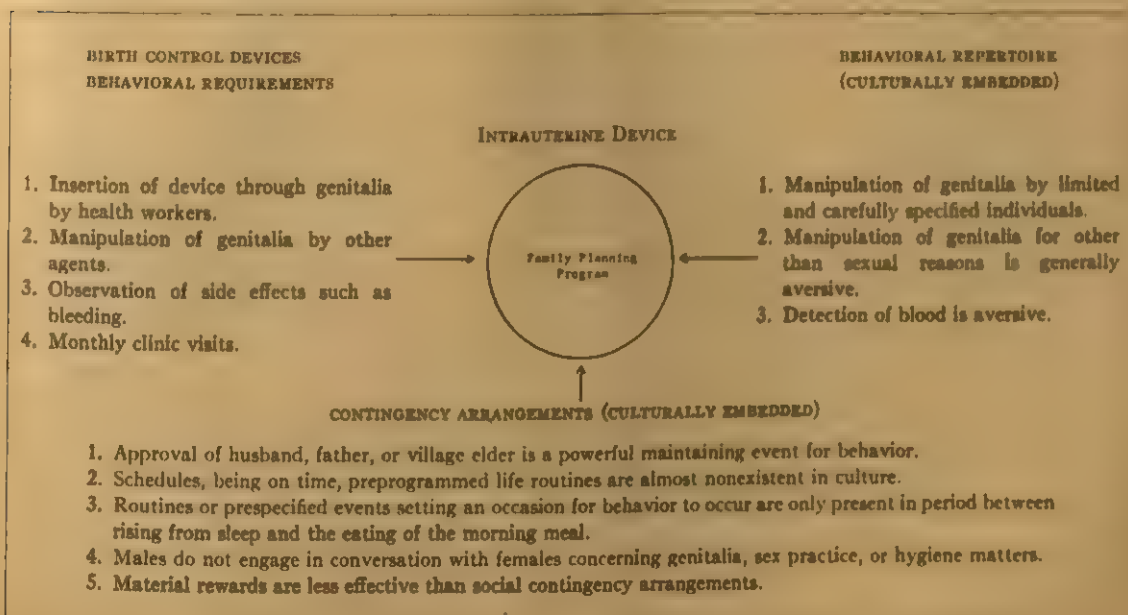

Ralph Linton (1959) defined culture as "the way in which man behaves." Culture generates and

supports behaviors, some of which are relevant to family planning. A culture generates consistent and predictable contingency arrangements as well as behaviors. Applied behavior analysis-based family planning programs must be behaviorally sensitive to the cultural context of a program. A behavioral taxonomy would identify all possible behaviors and contingency arrangements in a culture that might be relevant to family planning concerns.

In addition, every birth control device makes certain "behavioral demands" on its user. The chain of behaviors required for effective use of a condom is quite different than those required for oral contraceptives or an IUD (see display). Behavioral differences might relate to accessibility, self-management, spouse support, repetitiveness, contexts, etc. The development of effective family planning programs requires careful analysis both of the behaviors required for effective birth control device usage and those that members of the family are capable of performing. The interface of these two taxonomies can provide the family planning worker with a powerful decision-making base for the selection of behaviors and birth control devices for individual families.

A taxonomic manual for family planning can be developed, interfaced with an applied behavior analysis strategy and packaged in a format for ready employment by field workers.

Applied behavior analysis strategies are process based rather than problem based; that is, emphasis

is typically placed on applying a common process or technology across any problem behavior. Each new behavior entering into a problem definition does not demand a new set of analysis and change skills. A behavioral analysis might reveal that existing behaviors (life-style) in a Thai family might be capitalized on with the use of an IUD, rather than an oral contraceptive, and maintained with a culturally relevant incentive. In another family a behavioral analysis might reveal that a family's behavioral repertoire does not support an IUD, but is best capitalized on through the use of an oral contraceptive. In yet another family an oral contraceptive might be chosen, but because of severe behavioral deficits, the behaviors required to maintain effective usage must be installed and maintained. Behavior change programs for each family are developed with the same set of applied behavior analysis skills. Applied behavior analysis skills train workers to (a) define problems and solutions in terms of specific behaviors, (b) identify contingency arrangements that are functionally related to the desired behaviors, and (c) apply any or a combination of change strategies until program objectives have been achieved.

Thus the existence of certain cultural practices (behavioral repertoires) and the behavioral requirements of a given birth control device must be incorporated into planning for each family's needs. The use of applied behavior analysis strategies makes it possible to avoid subjecting individual families to unnecessary anxieties and obtrusive procedures in implementing a family planning program. Every birth control device, operationally speaking, makes certain behavioral demands on a family. Family planning workers, utilizing applied behavior analysis skills, can select a birth control procedure compatible with a family's behavioral repertoire or build a behavioral repertoire compatible with the existing birth control procedure. In either case, the happiness, stability, and integrity of the family may be maintained effectively while introducing such a radical change as family planning.

What seems most important is the point that potentially useful family planning programs may fail because science has not paid systematic attention to (a) the behavioral requirements of a given program and its interface with existing family behavioral repertoires and (b) effective methods to change family behaviors so as to increase usage of family satisfaction with birth control procedures.

Rudimentary shibboleths prevail in this area, for example, "just increase accessibility," "better information dissemination," "educate the people." The most sophisticated birth control device is simply not good enough if people do not use it, do not use it correctly, or do not continue to use it. Helping families to employ appropriate family planning procedures requires a technology that is as scientifically based as that employed in developing the procedures themselves. Birth control devices are not soft drinks, soap powder, or cigarettes. They are a very personal experience for family members and inextricably related to pervasive and long-lived value systems. The linkage between many individual psychosocial and religious parameters and the use of devices may well be the individual behavioral analysis of the behaviors related to the problem and the solution.

Animal Clinical Psychology

A Modest Proposal

DAVID S. TUBER *Ohio State University*
DAVID HOTHERSALL *Ohio State University*
VICTORIA L. VOITH *Ohio State University*¹

Animals have been intimately associated with man for thousands of years. Although this relationship has been dictated primarily by utilitarian considerations, its character has been greatly influenced by a practical understanding of animal behavior. Attendant upon the domestication of animals as a source of food were the skills that enabled early man to share both labor and leisure with many other species. The dog, for example, has had a particularly protracted and unique relationship with man for almost 10,000 years. Trained for tracking, retrieving, herding, protection, and sport, the dog has also served as a companion. More exotic creatures such as the falcon and hawk were trained for hunting and sport as early as 3,000 years ago. The training of animals solely for the purposes of entertainment has been practiced for at least 4,000 years and has encompassed a wide variety of species both domestic and wild. Thus, the development of the necessary training skills has proceeded in the absence of any formal discipline of psychology and, for the most part, continues to exist apart from it.

Although a seemingly natural ally, the field of experimental psychology shares no common heritage and seldom recognizes or examines this body of independently developed knowledge. In fact, it has been only within the last two decades that the experimental psychologist has emerged into the area of applied animal psychology. In 1951, Keller and Marion Breland used the *American Psychologist* as

a forum to enthusiastically announce the founding of a new area of applied animal psychology: commercial animal training. Stating that behavioral technology had now reached a level of development such that the efficiency of the new behavioral techniques would "outstrip old-time professional animal trainers [p. 202]," the Brelands envisioned an area of unlimited opportunities and financial benefits for experimental psychologists. Whereas the Breland's commercial venture, Animal Behavior Enterprises, has indeed flourished, a survey of modern dog training manuals reflects little modernization; the employment statistics for experimental psychologists with animal behavior backgrounds suggest even less improvement and much less hope (cf. the May 1972 issue of the *American Psychologist*).

Subsequent reports by other behavioral scientists have described the introduction of applied animal psychology into industrial and military settings. Skinner's (1960) experiences in training pigeons as organic missile control systems for the military are well known. More recently, Cumming (1966) and Verhave (1966) recounted similar experiences concerning the adoption of trained pigeons in industry for use as quality control inspectors. In all of the above cases, the quality of the technology in producing the desired behavior was successfully demonstrated. However, the reception by the military and the industrial reviewers was less than enthusiastic and the projects were terminated. Unfortunately, the optimism of the Brelands has not been borne out.

Ironically, experimental psychology has received acceptance in the extrapolation of behavioral principles to the modification of human behavior. Witness the current use of conditioning therapies in the treatment of phobic reactions (Wolpe, 1958) and in the treatment of retardates and more incorrigible mental disorders (Ulrich, Stachnik, & Mabry, 1966).

¹ The assistance of Donn W. Griffith, DVM, and the Ohio State University Veterinary Clinic is gratefully acknowledged. We would also like to thank our colleagues in experimental and clinical psychology for their support and encouragement.

Requests for reprints should be sent to David Hothersall, Laboratory of Comparative and Physiological Psychology, Ohio State University, 1314 Kinnear Road, Columbus, Ohio 43212.

Considering the outcomes of earlier ventures into the field of applied animal psychology, it is with guarded optimism and a tempered enthusiasm that we come before this readership to describe yet another endeavor: the application of psychological principles to the treatment of behavioral disorders in animals.

For the past two years, we have been engaged in this application of psychology. In this article we report on some of our efforts thus far and on the mechanics of a service which is functionally a clinical psychology for animals. All of our clients (pet owners) have been referred to us by veterinarians and, as such, have had their pets examined to ensure that the behavioral problem was not attributable to any underlying organic dysfunction. In most cases the origin of the behavior and the circumstances under which it first appeared are unknown or obscure. Typically, the problem has been allowed to persist untreated or has resisted treatment by more conventional means. Too frequently, we represent the final resort. Procedurally, we employ a team approach. Our various backgrounds (Hothersall: operant conditioning; Tuber: classical conditioning; Voith: veterinary medicine and conventional training techniques) are combined in the analysis of the behavioral problem, and a training program is developed that often represents a synthesis of these skills. We have found that the most efficient approach is to utilize the owner as the agent of change and the home as the training environment. Consequently, a considerable effort is concentrated on translating the program into an understandable terminology, devising practical analogies to a laboratory situation, and counseling the owner in the implementation of the program. When the owner contacts us concerning an appointment, he is requested to maintain a daily log detailing relevant information regarding the behavioral problem, the circumstances surrounding its occurrence, and any additional information that might be pertinent. The initial interview, attended by the pet and as many family members as practical, is used for obtaining a thorough case history, understanding the domestic environment into which the training program must be interjected, and providing an opportunity to observe the family-pet interactions. At a subsequent session, the owner or the person responsible for the training is presented with a written training program which elaborates on the rationale and describes in detail all relevant manipulations. This is then discussed and may even be

rehearsed with the owner. In addition, we provide daily training protocols and behavior records which are to be filled out by the owner as the training progresses. These are useful as training guides for the owner and are indispensable to any evaluation of the effectiveness of the intervention. They may merely confirm a success or identify the source of difficulty, hence affording the basis for a knowledgeable adjustment in either the program or the approach to the problem. All training programs are routinely evaluated with the clients after approximately three weeks of training.

The following case summaries describe the essential points of several pet problems that we have encountered; they are presented to characterize the flavor of our approach and the mechanics of our service.

Higgins

Higgins is an affable four-year-old Old English Sheep Dog of Goliath proportions whose tranquil demeanor was breached only by an intense fear of thunderstorms. At the first indication of an impending storm, Higgins would begin an accelerating pattern of aimless pacing, profuse salivation, and marked panting which was rapidly climaxed by the hurtling of his 110-pound body against any obstacle in a futile attempt to escape. A variety of confinement procedures and tranquilizers had been tried without success, and the behavior had continued unabated for two years. The crisis that threatened the relationship between Higgins and his petite owner occurred when they were forced to share the owner's foreign sportscar during a thunderstorm.

Since the fear was elicited by an identifiable and reproducible stimulus, a course of therapy involving counterconditioning in the fashion of Jones (1924) and Wolpe (1958) seemed most appropriate. Having satisfied ourselves that a stereophonic reproduction of a thunderstorm would elicit the fear—Higgins actually overwhelmed the three people in the room with him—the stimulus situation was presented in graded steps along the dimension of intensity. Beginning at an intensity that did not evoke the fear, Higgins was brought under command to lie down, and the subsequent occurrence of thunder was paired with a food reward of chocolate bars. As long as Higgins remained calm and maintained the antagonistic posture, the intensity of the recreated, artificial storm was gradually increased. Training was initiated in the laboratory

in daily sessions lasting one hour: The beginning intensity for each session was always slightly less than the terminal level achieved during the preceding session. We had been proceeding gradually with few difficulties; over the course of the first five conditioning sessions we had progressed from a thunder intensity level of a meager 35 decibels to that of a resounding 75 decibels when a typical summer thunderstorm intervened to test our efforts. Happily, the owner reported that Higgins initially exhibited only a mild version of the original fear response, that he was easily brought under control, and that she was able to successfully practice the training as we had done in the laboratory. Subsequent sessions in the home with artificial and real storms have succeeded in the further attenuation of the fear response. Realistically, we do not expect Higgins to ever seek pleasure in thunderstorms, but the change in his behavior has been striking and is at least compatible with his surroundings.

Hookie

A more difficult class of problems is concerned with the interruption of established misbehaviors that occur only when the pet is left alone. The behavior appears related inextricably to the absence of the owner, and consequently, any direct control over the behavior is precluded by the absence.

Hookie is an 18-month-old male Afghan whose owner necessarily left him alone for extended periods of time. Upon his return, the owner would find chewed clothing and furniture, a distribution of feces which was described as pernicious, and Hookie, wearing the appropriate expression of shame. The conventional remedy of confinement merely restricted the range of destruction. The punishment, which was necessarily delayed, proved ineffective. The initial interview, supplemented by a daily baseline log, suggested that appropriate manipulations of the prevailing stimuli would modify the behavior considerably. Preparatory to prolonged absences, during which destructive behavior invariably occurred, the owner engaged in an elaborate pattern of ritualistic acts that were intended to secure the house from without as well as from within. No such precautions were required either by absences of short duration or by Hookie's behavior during such absences. Therefore, a necessary part of the training program was to degrade the validity of both contextual and temporal stimuli

associated with prolonged absences. By introducing a stable, novel stimulus into the training situation, we provided a manageable cue to which acceptable behavior could become associated and could easily be maintained by training. Further, this training would provide a background against which we could extinguish the undesirable behavior. The new stimulus for Hookie's training was provided by a radio tuned to a local rock station which already had a strong association with the presence of the owner. The new response was simply any behavior other than that of the destructive variety.

Conceptually, the strategy is the expression of the operant reinforcement schedule differential reinforcement of other behavior under the control of a discriminative stimulus. Viewed as a transfer paradigm, this association between a new stimulus and new response has been shown by Wickens (1973, pp. 229-231) with cats to be immune to any proactive effects of a prior association. But more remarkable, such a new response appears to have deleterious retroactive effects in that it displaces the response of such a prior association over a long retention interval.

The mechanics of the training were relatively simple. A schedule of training absences was devised such that as training progressed, the average duration of the absences was gradually and variably prolonged. The initial absences were by design very short in order to minimize the occurrence of any misbehavior and to maximize the probability of intercepting and punishing it. During all absences the new stimulus was always present. Later in training, the cues formerly associated with extended absences were systematically introduced into the training situation. Good behavior on Hookie's part following an absence was always reinforced by the owner with an effusive greeting and a brief play session. Misbehavior was to be punished by a stern reprimand followed by a retreat to remedial training at shorter absences with only the novel stimulus. The owner laboriously followed our suggested training schedules, which often required two training absences each day accompanied by tedious cue manipulations. He was duly rewarded for his efforts. In the intervening four weeks between the final interview and the training evaluation, Hookie had violated the house only once despite the occurrence of several unplanned, extended absences by his owner. Accordingly, the training could safely be reduced to a maintenance schedule of several sessions per week.

Sandy and Jenny

A situation in which the determinants of an undesirable behavior were inherent in the very nature of unavoidable, energetic contact was resolved by the unique modification of the interaction between a small terrier, Sandy, and a three-year-old child, Jenny. Sandy nipped Jenny regularly during play and was becoming increasingly sensitive to all play such that the nipping was beginning to generalize to other children. The interview, which was attended by the parents, the child, and the dog, confirmed that the nipping was elicited by the normal excesses and unsophisticated style of the play itself. A training program was developed which was modeled after the children's game Simon Says. It involved teaching Jenny how to pet an inanimate object—gentle openhanded petting being rewarded with candy. Independently, Sandy was taught to sit on command for a reward of a slice of hotdog. When both were trained satisfactorily, they were brought together and the games were combined. Sandy was required to sit; Jenny was requested to approach Sandy and gently pet him only once. Both were then rewarded immediately. As the training progressed, the game became slightly more entailed in that Jenny was required to pet an ever-increasing number of different areas prior to obtaining her reward, and Sandy, by default, had to tolerate the ever-increasing amount of petting prior to gaining his reward.

The parent was the moderator of the game, the judge of correct responses, and the dispenser of the rewards. Progression to longer and longer schedules of interaction was determined entirely by the comfort and skill of the participants, which were carefully monitored and adjusted by the parent.

The game proved completely effective in eliminating the nipping, and we have suggested that an abbreviated version of the game should be practiced to prevent the recovery of the old play patterns. In addition, we suggested that the game be used as a vehicle for introducing new children to Sandy and ensuring their skill in handling the dog.

Cautions, Comments, and Other Considerations

Transporting the principles and methodologies of a behavioral science beyond the walls of the laboratory is a formidable challenge: refreshing, often rewarding, frustrating, and occasionally intimidat-

ing. We have experienced a form of culture shock. Gone are the controlled environments of the experimental chambers and the efficiency afforded by the most fundamental of instrumentations. Absent too are the security offered by group means and the closure provided by the control group.

Whereas in the laboratory one's research methodology is dictated primarily by the problem under investigation, the methodology selected by the animal clinical psychologist is disproportionately influenced by the sensitivities of the owner and his demands, the tenor and routine of an ongoing domestic situation, the physical surroundings, and the pet's relationship to all of these variables. The applied animal psychologist must be aware of, and be particularly adept at incorporating, just those variables that a good research strategy seeks to render ineffectual. What may be the treatment of choice may not be the treatment of convenience—and it is the latter that often determines whether or not a training program, no matter how ingeniously conceived, will be palatable to and consequently implemented by the owner.

Discovering inexpensive analogies of laboratory apparatus demands a similar ingenuity which leads one to explore the shelves of hardware stores and novelty shops. One quickly learns to appreciate the merits of a child's cricket when a conditioned reinforcer is desired. Stereophonic sound effects recordings are another resource when artificially reproducible stimuli are required by a training program.

To all of the preceding must be added the inescapable reality of economics. Overhead expenses dictate fees; fees mean ledgers, billing, and collection. Too often, the fees will be weighed against the cost of euthanasia—a very real consideration for some owners and consequently for the practitioner who must necessarily consider the pet as his primary responsibility. Fees also expose the experimental psychologist to a variety of agonies totally foreign to his academic background which has in fact shielded him or otherwise rendered him contraprepared. There are those clients who expect no fewer guarantees from their pet's psychologist than from their television serviceman, and more than from their family physician. The practitioner must learn by experience to expand the limits of his sensibilities. Fortunately, most clients are concerned, understanding, and often knowledgeably sophisticated about their animals and generally delight in them. Their acceptance of your efforts and

their willingness to pursue a sometimes arduous training program are mutually rewarding. The foregoing has been offered, not as a deterrent, but as a caution which must be given thoughtful consideration by any prospective practitioner.

There are an estimated 40 million dogs kept as pets in this country. Although the relative frequency of serious behavior problems is not yet determined, the responses from veterinarians in this area have been encouraging. It does appear that a need for such a service exists and that it is a legitimate extension of experimental psychology. Whether or not such a need can be satisfied by an applied area of animal psychology would seem to be determined largely by the efficacy of our technology and willingness of interested students to pursue such a career. The efficacy of the technology resides partially in the perceptiveness of the applied psychologist, but to a greater extent to the depth of his ties not only to the basic scientist but to his counterpart in the human clinic as well. There is a pleasing irony surrounding the adoption of a therapeutic treatment for a dog which was realized for use with human patients, based on principles generated by experimentation on dogs. The evolution of ideas, reflected in our treatment of Higgins, has been circuitous but advantageous.

We have already alluded to other contributions by the basic scientist to the applied area, but it is important to point out that the advantages of such an alliance are mutual. An example is the article "Misbehavior of Organisms" (Breland & Breland, 1961) which has emerged as a crucial element in the current reexamination of learning theory (Bolles, 1972; Hinde & Stevenson-Hinde, 1973; Seligman, 1970).

Ancillary but very pragmatic considerations have been suggested by Little (1972) regarding remedial measures precipitated by the dismal employment prospects for psychologists. The vulnerability of comparative and experimental psychologists within the academic marketplace might well be attenuated

by an area of animal clinical psychology. By expanding the employment opportunities at both the master's and doctoral levels, it would provide a means of maintaining a viable training program without resorting to a reduction in enrollments. In addition, it could also expand the traditional academic roles of psychologists to include schools of veterinary medicine.

We are aware of at least three other groups of psychologists and veterinarians who are currently engaged in behavioral applications similar to our own. Possibly there are more, and we hope that this article will initiate an exchange of information and communication between such groups. We are prepared to act as a clearinghouse for such needed interactions.

Eclecticism at Work

Approaches to Job Design

B. E. SANDLER *Center for Creative Leadership, Greensboro, North Carolina*¹

The nature of work in America is in the public eye. A great deal of attention has been focused on such things as job design, the quality of working life, job satisfaction, and productivity. An unprecedented opportunity exists for behavioral scientists to apply their skills to seeking solutions to the problems of industry. However, the opportunity is not without its perils. There are two primary dangers: first, that we will limit ourselves to using the approaches and techniques with which we are familiar; second, that we will use them in situations in which they are inappropriate. If we fall into either of these traps, we will fail to capitalize on the opportunities that exist to extend the limits of our knowledge and skills.

Job design has been a major focus of the more general concern about work. Numerous aspects of job design have been advocated, implemented, and reviewed (Davis & Taylor, 1972; Maher, 1971; Sandler, 1974). The coverage given many job design efforts by the popular press, media, and the professional literature is reminiscent of approximately 20 years ago. *Plus ça change, plus c'est la même chose.*

Certainly some things have changed, and in these changes lies hope. The changes, I believe, lie in the business climate—not within psychology. Changes in the international balance of payments, the industrial output of other nations, and the stridency of today's workers have made businessmen more aware of the need to find solutions to the problems facing them and more receptive to innovation.

Job Enlargement

Job enlargement, a term I am using in a generic sense to include enlargement, enrichment, and participative decision making,² has been a major approach to job design. Proponents of job enlargement see it as a way of reducing the high degree of specialization brought about by scientific management (Taylor, 1947). It is felt that reducing the amount of specialization will make the work more meaningful and satisfying and may result in desirable changes in productivity, quality, and other variables of interest.

Because job enlargement is typically presented as an approach of broad applicability, the question that must be asked is, To what extent can it be used to come to grips with the difficulties faced by American industry?

Job enlargement has been useful in some settings. Ford (1969), for example, described the use of job enlargement with more than 1,000 Bell System employees in 10 companies. Experimental and control groups were used in all but one instance. Four indexes of the effect of the enlargement projects were used: (a) technical measures of performance; (b) employee attitudes as determined by turnover, grievances, and questionnaires; (c) customer attitudes; and (d) manager's attitudes as determined by desire to drop or expand the project, or move the project to a permanent status. The results were generally positive, although one trial produced no change. Increases in the quality and quantity of work and reductions in turnover were common.

¹ I am indebted to R. C. Dorn, A. Lowin, and D. W. MacKinnon for their comments on an earlier version of this article, and to Linda Amme for her assistance in preparing the draft.

² One way of enlarging jobs is to increase the size of the job in terms of the number of operations performed. Another method is to permit the employee to take a part in decisions that affect him or his job. While these are different methods, the practical effect of both is to enlarge the province of things with which the employee is concerned. In this sense, participative decision making is a form of job enlargement.

The reactions of employees and managers to the job enlargement projects were, in general, positive.

In a study designed to determine the generality of job enlargement, Paul, Robertson, and Herzberg (1969) studied laboratory technicians, sales representatives, design engineers, and factory supervisors in a British company. As determined by various measures, job enlargement was applied successfully to all of these groups. Paul et al. concluded that job enlargement is a generalizable concept and is probably feasible in all settings. Furthermore, they felt that the gains from job enlargement are significant and lie primarily in the area of job performance.

However, Hulin and Blood (1968) believe the case for job enlargement has been overstated. After a review of the literature, they concluded that

the argument for larger jobs as a means of motivating workers, decreasing boredom and dissatisfaction, and increasing attendance and productivity is valid only when applied to certain segments of the work force . . . [p. 50].

While this position has been questioned (e.g., Shepard, 1970), the fact that industry continues to focus on job enlargement indicates that it is alive and well, in spite of inconclusive data.

Although more data are needed for a better understanding of the manner in which psychological and sociological factors affect workers' responses to job enlargement, one suspects that the limitations on applicability imposed by these factors are relatively minor compared to those imposed by technical and economic variables. Levitan and Johnson (1973) discussed the way these factors may limit the ability to alter jobs. They pointed out that technology is an important factor in determining job design and emphasized that changes which necessitate the replacement of expensive capital equipment are unlikely to be made.

Two of the major concerns regarding job enlargement are that it may reduce productivity and increase costs. While these concerns have not been problems in the reports that have appeared (e.g., Ford, 1969; Paul et al., 1969), one suspects that cases in which problems have arisen may not have been reported.

The attitudes of managers are another variable affecting the implementation of job enlargement programs. Bucklow (1966) indicated that still another impediment to the implementation of job enlargement is the "unquestioned acceptance of the methods and assumptions of scientific management and the traditional management theorists [p. 74]."

In view of the limitations that technical, economic, and attitudinal factors pose to broad-based programs of job enlargement, it is necessary to investigate other approaches. We must work to conceptualize the problem in ways that promise more broadly applicable solutions to the problems of industry.

Modified Workweeks

Modifications of the standard five-day workweek have been initiated by a number of diverse firms. The response to the modified workweek has been generally positive—on the part of both employees and management. The modified workweek appeals to management because it leads to reduction in the cost of doing business, either through increased production, decreased turnover, decreases in start-up and stop time, increased motivation, as well as other variables as yet to be identified.

The modified workweek appeals to employees because it redistributes their free time into more meaningful patterns. Although an employee may work the same number of hours under a modified schedule (say 40 hours) as he did previously, he is now doing it in fewer days (say 4 instead of 5). The result is an effective increase of time at essentially no cost to the worker. The redistribution of time into more meaningful groupings comprises the essence of the modified workweek.

Many of the reports that have appeared have been merely descriptions of the modified workweeks, summaries of the experiences of companies on it, and methods for converting to it (e.g., Hellriegel, 1972; Poor, 1970). In a longitudinal study of worker adjustment to the four-day workweek, Nord and Costigan (1973) found that overall attitudes to the four-day workweek were highly favorable. Absenteeism decreased following the introduction of the modified schedule, and then decreased more by the end of the study. Differential effects of the four-day workweek were found to be associated with age, plans for the use of nonwork time, and job pace.

Clearly, the modified workweek can result in significant gains for all concerned. The questions that must be considered are, How broadly applicable is the modified workweek? and What is the long-range outlook for it?

The modified workweek has broad applicability. Modifications can be made, at least in theory, in the workweek of virtually all employed persons. Of

course, there is a gulf between theory and practice. For example, labor unions have been staunchly opposed to modifications of the workweek that result in an increase in the length of the workday. Thus, the 4-day 40-hour schedule has been opposed by most unions. Whether union resistance represents a long-term problem or merely a temporary restraint to alterations in the workweek remains to be seen.

Another impediment to the modification of the workweek is the existence of laws, both state and federal, which regulate hours. These laws, and the bureaucratic procedures necessary to demonstrate compliance, are enough to cool the ardor of all but the bravest (or most troubled) innovator. These laws may restrict the speed with which modified workweeks are adopted. However, as the modified workweek gains in popularity—and every indication is that it will continue to do so—increased pressure for modification of restrictive legislation can be expected.

If the modified workweek is inevitable, the most important question is, What are the long-range prospects of it in terms of employee satisfaction, motivation, production, and other variables currently being affected by changes to modified work schedules? Clearly, it is only possible to speculate.

When the modified workweek becomes the norm, it will, by definition, no longer be novel. When almost everyone is working a schedule that results in more meaningful groupings of free time, the perceived value of the schedule will likely decline for all. It is hypothesized that one of the values of the modified schedule is that it affords the individual who is on it prestige, status, and recognition (relatedness needs in Alderfer's, 1972, ERG—existence, relatedness, growth—theory). These values, in addition to the more effective time distribution, contribute to the effectiveness of the modified schedule. With increased adoption of modified schedules, these relatedness needs will no longer be satisfied by the schedule per se. Hence, one could predict an increase in turnover, absenteeism, decreased production, etc. As modified workweeks of all sorts become more available, one of the important barriers to employees leaving a firm operating on a modified schedule is also removed, since a position with another firm on a modified schedule is relatively easy to find. That is, it is hypothesized that as modified workweeks become more widely available, they will become increasingly less effective, but more necessary.

Modified work schedules—modified in the direction of greater flexibility and a more useful distribution of leisure time—are probably destined to replace the now standard five-day schedule. If our hypothesis is correct, they will lose some of their effectiveness as motivational tools in the process. They may, however, serve to make work, especially unpleasant work, more palatable by reducing the amount of "psychological time" that must be devoted to it. This possibility needs to be explored and tested.

The Problem Solver and the Problem

The question of how to achieve a broadly applicable solution to the problems facing industry still remains. The methods discussed above are useful, but have limited applicability either spatially or temporally. Where do the answers lie?

Discussing potential solutions is premature without first discussing the problem solver (the psychologist or the executive) and the problem. Campbell (1969) discussed the former. He distinguished two types of individuals. The first, referred to by Campbell as the *trapped administrator*, has committed himself in advance to the efficacy of the solution and, consequently, is committed to it. The *experimental administrator* (or psychologist), however, has justified the solution on the basis of the importance of the problem. As a result, he is committed to seek other solutions if the first one fails. Thus, our first recommendation is that in seeking solutions to the problems of industry, one would do well to attempt to emulate Campbell's (1969) experimental administrator.

Perhaps the most difficult part of implementing an effective solution is finding a fruitful problem. The importance of problem finding and problem formulation is gaining increasing attention (Csikszentmihalyi & Getzels, 1971; Getzels & Csikszentmihalyi, 1974; McGuire, 1973; Taylor, 1972). There are problems and there are problems, and the goodness of the solution is related to the goodness of the problem that has been selected.

One method of developing problems is through the process of transformation (Taylor, 1972):

It can be asserted that only simple problems lend themselves to direct solution processes, and that complex problems, if they could be solved directly, would already have been solved. Complex problems require complex solution process, or processes which transform these problems into forms that allow for solution. Transformation processes as an approach to rendering problems soluble include reversals,

Our lack of success in dealing with the troubles of industry may stem from our failure to transform the problems as they are seen and presented by management into forms that allow for solution. For instance, the problem of monotonous and repetitive jobs has long troubled industry and industrial psychologists. Solutions have been attempted by dealing with the problem directly and trying to modify the nature of the job. Perhaps more fruitful solutions would emerge if the problem were stated differently, thus allowing for unrecognized solutions as a result of the transformation.

The problem of repetitive and monotonous jobs can be transformed to one of the perceived speed with which time seems to pass. That is, the job is seen as boring because too long a period of time is spent doing it. Since time passes slowly, the undesirable features of the job are amplified psychologically, and their negative valence affects the entire job. If the speed with which time seemed to pass could be increased, these difficulties might be overcome. Monotony and repetitiveness may be important variables affecting the perceived passage of time. However, research might discover additional variables that could be manipulated effectively to affect the perceived passage of time. The focus of the problem is no longer on changing the nature of the job but on the variables that affect the passage of time. This transformation may result in a form of the problem that allows for a more fruitful solution. If not, other transformations and other solutions must be tried (à la Campbell, 1969).

Toward a Psychology of Responsiveness

Increasingly our society is becoming more permissive with regard to the freedom of the individual to meet his needs in the manner most appropriate and satisfying to him. This permissiveness, embodied in the colloquialisms "do your own thing" and "whatever turns you on," has found expression in many aspects of life. Work has been one of the notable exceptions. Work has remained a last outpost of rigid conformity to an arbitrary, and perhaps sacrosanct, set of standards. The assumptions underlying the standards are never questioned. It matters little whether the assumptions are those of Theory X or Theory Y (McGregor, 1960). Proceeding on the basis of either theory is bound to ignore the vast body of data regarding individual

differences. No unitary approach can successfully address itself to the full range of variation represented by the employees of a given business—even a small one. But, while an organization cannot afford to function in a manner designed to be all things to all men, it is possible for organizations to be more flexible and responsive to the needs of their members.

The need for a variety of executive compensation plans, and flexibility in modifying and implementing those plans, has long been recognized. The assumption has been that the needs of the executive should be a factor in determining the nature of the compensation package, and that the investment made by the organization in the individual's compensation package would be realized through effective performance. These are reasonable assumptions—for the executive as well as for the man on the line. The possibilities available as a means of increasing the responsiveness of the organization to the needs of its members are limited only by the scope of those needs and the willingness of the organization to innovate.

The approach that promises the greatest amount of responsiveness to employee needs (as determined by the employee himself) is what may be described as a cafeteria approach, in which the employee selects from a number of alternatives those most appropriate for him. Certainly, the nature and number of alternatives offered would have to be based on an analysis of probable costs and benefits. However, in the absence of contradictory evidence, there is no reason why the cafeteria approach to employee need satisfaction could not prove as practical as the cafeteria approach to food service.

Adams and Solaski (1964) investigated an aspect of the cafeteria approach to employee need satisfaction in a study of the psychological value of compensation increase options. The options used in the study are as follows:

OPTIONS WITH A COST OF ABOUT \$600 TO COMPANY³

1. \$600 salary increase; no vacation increase; no increase in company contribution to employee savings plan.
2. No salary increase; 12 additional days of vacation; no increase in company contribution to employee savings plan.

³ These items are adapted from *The Psychological Value of Compensation Increases Options among Exempt Salaried Employees* by J. S. Adams & R. R. Solaski, General Electric Behavioral Research Service, New York, 1964.

3. No salary increase; no vacation increase; increase in company contribution to employee savings plan from 3% to 9%.

4. \$300 salary increase; 6 days vacation increase; no increase in company contribution to employee savings plan.

5. \$300 salary increase; no vacation increase; increase in company contribution to employee savings plan from 3% to 6%.

6. No salary increase; 6 additional days of vacation; increase in company contribution to employee savings plan from 3% to 6%.

Each participant in the study was told to assume he would get a raise in the form of one of these six options and was asked to choose among them. Adams and Solaski then determined the psychological value of each alternative and compared it with that alternative's real value and cost to the company. Only one option—\$300 plus 3% savings—had a psychological value greater than its cost to the company. But the ratio of psychological value to estimated cost to the company indicated two additional alternatives that were more attractive to the employee and the company than a straight salary increase. These were \$300 plus 6 days of vacation, and 6 days of vacation plus 3% savings.

Comparison of the psychological value of single components, the sum of these components, and the psychological value of the combinations, indicated that the value of the combinations was greater than the sum of their parts. That is, the psychological value of \$300 plus 6 days of vacation was \$97 greater than the sum of its components. The psychological value of \$300 plus 3% savings, and of 6 days of vacation plus 3% savings, exceeded the sum of their components by \$96 and \$81, respectively:

The increased value of combinations over what naturally might be expected is substantial. As a percentage of the expected value, the psychological value of the optional combinations is 17 to 20 percent greater. The exact reason for this significant interaction of option components is not known, but a likely explanation is that an option containing more than one form of compensation is more apt to satisfy individual needs since individuals have several needs [Adams & Solaski, 1964, p. 11].

Adams and Solaski's (1964) work has been considered in some detail because it is one of the few studies available addressing itself to the cafeteria approach to employee need satisfaction. (Also see Adams, 1962; Lawler, 1971; Mahoney, 1964; Nealy, 1964; Nealy & Goodale, 1967; Shuster, 1969.) Adams and Solaski's data are suggestive in that they appear to indicate that organizations may be able to make more effective use of their employee compensation resources by increasing the flexibility with which those resources are utilized.

The possibilities in extending the cafeteria approach to other aspects of the organization are exciting and may hold the promise of increased satisfaction for both the organization and its employees.

One possible aspect of the cafeteria approach, which utilizes aspects of the modified workweek as well, is the introduction of flexible working hours (Bolton, 1971). To date, this approach has been used more widely in Europe than in the United States. A recent article in the *Wall Street Journal* (Wong, 1973) reported the experiences of a number of American firms with flexible working hours. The essence of the approach is that it permits the employee to select the hours he will work, as long as he abides by certain rules regarding earliest and latest starting and quitting times and total hours worked. Certain plans permit employees to work a greater or lesser number of hours during a given period, with a resulting credit due them (in terms of time off) or debt owed by them (in terms of additional work time). The experiences of the firms interviewed by the *Wall Street Journal* indicate the use of flexible working hours appears to be a great success in terms of employee satisfaction and reductions in tardiness and absenteeism. Moreover, it represents some data concerning the feasibility of using a form of cafeteria approach in a variety of different settings.

There is reason to believe that the cafeteria approach could be broadened to include the work patterns of the employee. To do this it would be necessary to develop a number of alternative work patterns (data collected from the employees in a manner similar to that used by Adams and Solaski, 1964, would be useful in this regard) and then let the employees select the alternatives most appropriate to them. In a paper entitled "The Work Module: A Proposal for the Humanization of Work," Kahn⁴ developed a type of cafeteria approach to organizational design. Lawler (1973) also discussed the issues inherent in recognizing and accepting the existence of individual differences in the work place and their implications for a cafeteria approach to organizational design.

The nature of this approach can be illustrated

⁴ An unpublished paper by Robert Kahn, entitled "The Work Module: A Proposal for the Humanization of Work," may also be viewed as representing another version of the cafeteria approach. It is available from the Survey Research Center, University of Michigan.

using the differences between job enlargement and the unenlarged job. When a job enlargement program is put into operation, it is not unusual to find a subset of the work force who would prefer to perform the repetitious, unenlarged, familiar job (Argyris, 1973). Their reasons for this might range from resistance to change to enjoyment of the repetitiveness of the function they are performing. While the reasons for the differing preferences may be interesting, and perhaps worthy of study in their own right, they need not concern us. Rather they can be taken as an indication that different individuals see different types of activities as most satisfying to them. If the legitimacy of this is accepted—and we do not feel a missionary zeal to proselytize for what we “know” to be “right”—the implication is that we should establish two alternatives or options. One option would utilize a job enlargement approach; the other would retain the previous job design. If the system is also designed to permit and encourage flexibility (perhaps evolution would be a better term) we might find people switching from one option to the other as their needs, or their perception of the most effective way to satisfy them, change. As this occurs, the employees could play a role in the development of new alternatives, thereby helping the organization evolve. This would represent the stage that Land (1973) referred to as *mutual growth*.

In evolving toward greater mutual growth, the organization must continue to recognize the legitimacy of patterns of behavior and need satisfaction with which it might disagree. It should not sit as an arbiter of behavior through, for example, implicitly supporting the Protestant ethic. Rather, it must permit and encourage its employees to grow in the manner most appropriate and satisfying to them, with the only *quid pro quo* being certain specified criteria of performance.

The process through which this goal is achieved will necessarily be one of successive approximations. Job enlargement, participative management, modified workweeks, and flexible hours can be viewed as intermediate stages. We can only speculate as to what forms the alternatives that could be established might take. However, the speculation is interesting, and fruitful hypotheses can be derived from it.

For example, an organization might establish three alternative work patterns. Option 1 might be for those individuals who are interested only in putting in a given number of hours in return for

their pay, with no desire for advancement. Salary increases might be given at periodic intervals, contingent upon certain specified criteria, until a maximum is reached. Nothing is expected of these individuals, either explicitly or implicitly, except a specified level of performance. Option 2 may differ from Option 1 only in that it utilizes a modified workweek of some sort. Option 3 could be established specifically for those individuals who desire to advance to supervisory positions. While the entry work (and wages) for this option might be identical with Options 1 and 2, it would be known to all employees that supervisory personnel would be selected from among the employees choosing Option 3.

Other options could also be developed. These might make use of job enlargement, participative management, performance contracting, or a host of other alternatives. It is not my intention to attempt to develop a list of feasible options, but rather to consider the merits of the approach.

In a given organization, a substantial number of employees might choose Options 1 and 3. In doing so they would be responding to the alternatives in a manner calculated to either maximize or optimize their personal need satisfaction. Under these circumstances the organization is set up to encourage such behavior. Usually, however, the organization discourages this type of behavior because there is only one work pattern and everyone is required to fit the pattern at some minimally acceptable level or leave the organization. Certainly no one is naive enough to assume that employees will not engage in attempts to maximize personal need satisfaction just because the organization may discourage them from doing so. It is likely that the result will be either covert attempts at constructive satisfaction, or covert attempts at destructive satisfaction through increased waste, downtime, sabotage, etc.

The employee who wishes to “look good” and wants to advance is also in a difficult situation. Improved performance on his part is likely to violate unspoken understandings regarding productivity, and peer group pressures will be mobilized to return him to the fold. If he succeeds in resisting these pressures, he is likely to be ostracized from the group. If he subsequently is given supervisory responsibility, this is likely to make his position considerably more difficult.

It can be hypothesized that the present work pattern which throws together people with vastly differing needs and aspirations may exacerbate con-

fluct between them and serve to limit the effectiveness of their performance. On the other hand, a cafeteria approach which results in a relatively homogeneous grouping of people according to their needs and aspirations may reduce conflict and remove some of the factors limiting effective performance.

Implementing a multiple track system might prove difficult, at least initially. Designing in the type of flexibility that would permit an employee to switch tracks as his circumstances, needs, or perceptions changed would also be difficult. It may be easier for organizations with a number of separate locations to implement this system than would be the case for a small company with only one plant. The approach is probably applicable to both. Establishing this type of diversity across organizations might be reasonably effective in better meeting the needs of employees, but not in meeting those of the organization. To meet both individual and organizational needs, the diversity must exist within an organization. However, as organizations develop and implement more effective ways of meeting employee needs, they are likely to be rewarded with the type of improved performance for which they have been searching.

Statistics

Tool or Master of the Psychologist?

ANTHONY SIGNORELLI *Union College*¹

Psychologists, when discussing the historical development of their endeavor, frequently note its roots in philosophy and as frequently proclaim that it is gradually attempting to emulate the physical sciences in divorcing itself from this parent by becoming more quantitatively and qualitatively precise. That a science of psychology is progressively evolving is evidenced, it is often claimed, by the fact that it has increasingly embraced a mathematical tool—statistics—for use in evaluating its postulates. What is overlooked is the fact that the use of mathematical tools in the development of the physical sciences bears little resemblance to the use of statistics in psychology. Statistical procedure has influenced theory, the direction of research, and instrumentation in psychology to an extent and in a manner foreign to the influence of mathematics on the physical sciences.

While it is true that many of the postulates of prominent theories in psychology were not based on statistical evidence, it is becoming increasingly popular to construct theories based on, and embodying, statistical formulation (e.g., Estes' learning theory, Feigenbaum and Simon's explanation of the serial position curve, and John's hypothesis of memory storage). In addition to theorizing statistically, attempts to prove theories or to rebuke their alternatives are relying on statistical design with growing frequency. Perhaps this preoccupation with statistical procedure has invaded experimental psychology more pervasively than any other division of psychology, although no division is uncontaminated.

A common procedure of the experimentalist is to apply a treatment—which a theory suggests or which he believes, at the suggestion of the theory, will influence behavior in some manner—to a group

of subjects and compare the results of their performance against the performance of subjects not receiving the treatment. The comparison is a statistical one that measures the sufficiency of the difference between the numerical averages obtained from the two groups to determine if it is due to chance or treatment.

This "test of significance" procedure, which has become the keystone of experimental research design, has been criticized by several authors (Bakan, 1966; Bolles, 1962; Edwards, 1965; Meehl, 1967; Rozeboom, 1960). The procedure is founded on the belief that since the groups to be compared are randomly selected, any chance, unknown, or unmeasurable factors that may influence differences in performance will be equally distributed between the two groups and will thus be nullified when the comparison is computed. Any difference that results can then be attributed to the treatment under study. The main thrust of the criticism of the above authors was against the acceptance of this "null hypothesis" syndrome. Bakan (1966) noted that the probability of the null hypothesis occurring is extremely small under any circumstances. If, in fact, all extraneous factors were controlled by random sampling, then one should expect no subject in the control group to demonstrate behavior of the kind supposedly produced by the treatment under study, and each subject in the experimental group to demonstrate it. Since this ideal does not occur, probability limits are arbitrarily established so that one may demarcate between chance and treatment effect. This procedure is not entirely satisfactory. As Bakan pointed out, the deviation from the null hypothesis has a tendency to increase with an increase in the number of subjects utilized in the experiment. Since the significance of the results is dependent on the size of this deviation, the probability of obtaining significant results increases with sample size, regardless of the validity of the hypothesis under study. Yet, increasing sample size so as to obtain a "truly representative"

¹ Requests for reprints should be sent to Anthony Signorelli, Union College, Springfield Avenue, Cranford, New Jersey 07016.

sample is a procedure recommended by the majority of statistical textbook authors.

Bolles (1962) pointed out that a significant finding cannot be interpreted as necessarily supporting a hypothesis:

statistical rejection of the null hypothesis tells the scientist only what he was already quite sure of—the [subjects] are not behaving randomly. The fact that the null hypothesis can be rejected . . . does not give E [the experimenter] an assurance of . . . his particular hypothesis, but only that some alternative to the null hypothesis is true [p. 642].

Clearly, if factors, which one is either unaware of or unable to control, influence the outcome of the experiment, then one cannot with any certainty know the extent or the nature of their influence, nor contribute the results of an experiment to the specific treatment studied rather than to such factors. In spite of this ambiguity concerning the meaning of the results obtained from such experimental design, theoretical propositions are often considered confirmed or negated by them. Meehl (1967) wryly noted:

review articles which purport to survey the current status of a particular theory in the light of all available evidence, treat the confirming instances and the disconfirming instances with equal methodological respect, as if one could, so to speak, "count noses," so that if a theory has somewhat more confirming than disconfirming instances, it is in pretty good shape evidentially [p. 112].

This totting up of statistically significant results, pro and con, to a particular hypothesis often fosters unnecessary and unproductive research. In addition, this reliance on significance frequently blinds psychologists to implicit implications of experimentation and leads to controversies that are not resolvable at the level on which they are engaged. One such example is the controversy of the definition of reinforcement as consummatory response or as drive reduction.

An experiment performed by Sheffield and Roby (1950) demonstrated that a nonnutritive, sweet-tasting substance (saccharine) was a sufficient reward stimulus in a conditioning situation. Since saccharine obviously did not relieve hunger, the experimenters concluded that reinforcement could not be defined as a stimulus or an event that led to drive reduction. They proposed instead that the eliciting of the appropriate response was the primary reinforcing factor.

Miller and Kessen (1952) responded to this finding with an experiment that they suggested failed to support the Sheffield and Roby hypothesis (1950). They injected either milk or a saline solution directly into the stomachs of rats via a stomach

fistula. The rats were placed in a T-maze and rewarded with milk if they selected the correct side, and with a saline solution if they ran to the incorrect side of the maze. The animals demonstrated a significant preference for the milk side of the maze. The authors concluded that the drive-reducing properties of the milk were reinforcing, a conclusion that, of course, supports the drive reduction hypothesis.

Subsequent to the above reports, a series of experiments attempting to demonstrate the superiority of one or the other of the two hypotheses have been published, all with the appropriate statistically significant results. If, however, the obvious is accepted—that both findings are valid rather than mutually exclusive—it would be clear that what is necessary is not further experimentation with compilations of statistics, but a definition of reinforcement that is adequate to account for both findings.

The statistical significance of an event is largely dependent on the frequency of its occurrence. Thus, event frequency has become an important aspect of psychological study. Many research hours are spent producing frequent and repetitious events or seeking averages of observed behavior under the assumption that in this manner the lawfulness of the behavior or the principles thought to be basic to the causation of the behavior will be discovered. This tenet is evident, for example, in Skinner's methodological approach to learning. Skinner (1950) has suggested that the rate of response reflects the rate of learning. He, therefore, advocates the study of input variables and their influence on the rate of responding. By so doing he believes lawful relationships between the input and the response will be discovered, allowing psychologists the ability to predict and possibly to control behavior. Clearly evident in this approach is the idea that frequent correlation (between input and output) defines lawfulness. Further, the belief that repetition (of responses) reveals a basic process (learning) is obvious.

That the frequency of an event defines its nature is not a belief unique to Skinner. It is a prevalent belief in psychology. Levels of intelligence are defined by the frequency of occurrence, that is, that which is normal occurs most frequently. The frequency of the manifestation of particular behaviors often defines the category of mental illness and, in general, the average behavior observed—be it in the study of children, adults, animals, or classes of behavior such as personality or social intercourse—

is assumed to represent the essential or normal behavior applicable to the population observed.

Another prevalent influence of statistics on the practice of psychological research has been the willingness of psychologists to accept with no apparent discomfort the concept of chance. Because frequency defines the normal or essential, the infrequent event is considered abnormal or accidental. In an experimental situation, for example, the effect of a treatment under study is seldom demonstrated without exception. Provided the exceptions are at a sufficiently low level of significance, they are usually credited to chance. What is disturbing about this approach is the fact that psychologists seldom demonstrate a desire to seek explanations for chance results. Sheffield and Roby (1950), for example, found that satiated animals as well as hungry animals demonstrated a preference for saccharine over plain water. However, the hungry animals ran significantly faster and drank significantly greater amounts of saccharine than did satiated animals. If one accepts the performance of the satiated animals as due to chance, no further explanation is required. But if one accepts the performance as fact, then it is necessary to explain why animals, who were motivated by no apparent "hunger drive," nevertheless demonstrated "learning." Similarly, Miller and Kessen (1952) labeled as *error* a rat's preference for the saline side of the T-maze on any particular trial. It is *error* apparently due to the fact that it occurred significantly less often than the event of the rat approaching the milk side of the maze. There is no attempt to explain or to investigate the cause of such error—undoubtedly it is a chance event! The paramount importance of the statistically significant result caused investigators to virtually ignore seeking explanations for any nonsignificant findings. *Chance* is a euphemistic term for *ignorance*. The continued failure to investigate chance results, or factors that lead to such results, will in no way alleviate this ignorance.

Over 40 years ago Lewin (1931) published an article in which he suggested that the concepts and methodology of psychology resembled Aristotelian physics rather than Galilean or post-Galilean physics. Aristotelian physics, he noted, was deeply concerned with classification of objects and events. An object or event was designated as a member of a class by virtue of the number of characteristics or properties it displayed in common with other events or objects. This classification process was essential

since laws governing the behavior of objects and events were considered limited to specific classes—lawfulness was not universal but class dependent. So, for example, laws governing rocks differed from those governing feathers. One of the criteria applied in Aristotelian physics for establishing the laws underlying behavior was frequency or repetition. Events that occurred regularly and repeatedly were considered lawful; the unique event, it was believed, resulted from chance.

Similarly, psychologists are concerned with classification of human events. Behavior is classified into categories such as normal or abnormal, learned or innate, motor or verbal, memory, perception, etc. Average characteristics or properties for each of the classes are enumerated, and distinct principles or laws are sought. As with Aristotelian physics, frequency or regularity of occurrence is a vital criterion for the establishment of lawfulness; the unique or infrequent event is credited to chance.

The Galilean approach to physics rejected the concept that lawfulness is limited to specific classes. Rather, it was based on the philosophy that all events and objects are governed by universal laws. Classification of events or objects is not of primary importance since their behavior is not governed by virtue of their membership in a class but by laws that apply equally to all objects or events. Given the fact that laws apply universally, it follows that the unique as well as the frequent are amenable to lawful explanation. In addition, lawfulness is not primarily predicated on the frequency or repetitiveness of observed events. Rather, laws are abstract principles that can be applied to actual events. As Lewin noted, Galileo did not formulate the law of falling bodies by calculating an average from numerous, repetitious events. Instead, he deduced an underlying factor that was common to all falling objects. One cannot observe the law he derived from frequent observation of numerous falling bodies. In fact, one can observe the descent of falling bodies of different "classes" at equal velocity only in a vacuum, that is, under controlled, experimental conditions. The physicist thus uses experimentation to demonstrate the validity of a law, to show its application under various conditions, or to demonstrate an exception to the law. The psychologist, on the other hand, performs much of his experimentation or records numerous observations of events in the hope of discovering or detecting in the data lawful relationships. In general, such laws, which are thus apparently discovered, apply

only to a limited class of events rather than to the totality of behavior.

Since laws can be applied to unique events in physics, any demonstration of an exception requires that the law be revised or abandoned; the exception cannot be credited to chance. Physical laws are, thus, much more vulnerable to attack than are psychological laws. Because most of the evidence, pro or con, concerning psychological hypotheses is collected via statistical procedures and demonstrates the validity or incorrectness of the hypothesis on a probabilistic basis, it is most difficult to demonstrate a flaw in a concept with a single exception. Any such negative result can be considered a chance finding. In addition, since laws are class dependent, negative results can be rejected because they fail to measure the class of events they purport to measure.

Lewin (1931) suggested that the distinction between Aristotelian and Galilean physics is not the mathematical formulations of the latter. While Aristotelian physics did not utilize mathematical tools, Lewin believed statistical concepts were imbedded within its procedures. The measure of central tendency is readily applicable for abstracting the common characteristics of a class of events; tests of significance are excellent for demonstrating differences between classes; correlative statistics can be applied to events within a class to demonstrate their repetitive, covariant nature. In Galilean physics, mathematical procedures do not produce concepts but are utilized to add preciseness to the concepts.

Statistical procedure leads to the measure of generality and probability. Formulations extracted from their results are stated in terms of probability and are thus imprecise. The calculation of averages tends to result in the establishment of classes that are depicted as independent and mutually exclusive, and the belief that frequent observation is required for the demonstration of lawfulness is fostered.

The pervasive influence of statistics in psychology can even be observed in the development of its instrumentation. In physics the instrumentation is designed in accordance with physical concepts. While mathematical or numerical values are an important part of the instrumentation, they are not absolutely essential. For example, the ohmmeter, which measures the resistance to electrical flow offered by a resistor, is designed from concepts developed by Georg Ohm concerning electrical en-

ergy. While it indeed has a numerical scale to measure the amount of resistance, this scale is not an indispensable part of the instrument; one might also utilize a scale of hieroglyphics. The numerals add precision to the measure, they do not influence what is measured. In psychology, instrumentation is influenced by statistical concepts. The Skinner box is designed not to measure the presence of such theoretical factors as intensity of drive or reinforcement; rather, it is designed primarily to measure the frequency of the response. Intelligence tests and personality and diagnostic scales require the compilation of averages and correlative statistics to produce classifications and to demonstrate reliability and validity of the scale; the factor under measure is inferred from the power of the statistical results.

While there are psychologists who firmly believe that theirs is a science soon to be comparable to physics and who suggest that the use of mathematical tools demonstrates this approaching equivalence, it is clear, as Lewin (1931) emphasized, that psychology as it is presently structured bears closer resemblance to Aristotelian physics than to contemporary physics. Considering the futility of experimentation that evolved from the Aristotelian philosophy, in addition to the dearth of knowledge it bequeathed to future generations, it would behoove psychologists to reexamine the influence of their procedures on the underlying philosophy of their science.

Multiple Testing and Type I Errors:

A Reply in Defense of Multifactor Designs

Perhaps the relationship between multiple testing and the Type I level of significance bears repeating, yet the article by Udolf and Raymond (December 1973) is a cursory and misleading presentation of the problem.

The question of multiple testing and Type I error rates was brought to the attention of psychologists in the late 1950s by Ryan (1959, 1962). Since the first Ryan paper, the question has received a considerable amount of discussion (Games, 1971; Kirk, 1968; Levin & Mara-scuiolo, 1972; Miller, 1966; Myers, 1972; Perlmuter & Myers, 1973). Therefore, the effects of multiple testing and the compensatory procedures, whether computing multiple t or F tests, is well documented.

Udolf and Raymond (1973), on the other hand, suggested that to "eliminate problems encountered with shrinking significance levels in the face of multiple F tests . . . it is simpler and more precise to conduct an independent experiment for each independent variable of interest." Since the time of Fisher (1935) it has been known that factorial experiments are more precise and simpler to manipulate than one-at-a-time experiments. Even if one does not suspect an interaction effect and does not even choose to examine for such effects, it is incomprehensible how two consecutive experiments in which two separate sets of subjects must be randomly selected and assigned can be considered simpler than a single randomization schema for a factorial design. In addition, factorial experiments are more efficient than one-at-a-time miniexperiments in that the treatment factors are evaluated with the same precision by means of

only a fraction of the number of observations than would otherwise be necessary (Fisher, 1935).

Besides misrepresenting the relationship between factorial and one-variable-at-a-time experiments, Udolf and Raymond (1973) appear to be confused about error rates since they recommend substituting one multiple testing sequence for another. That is, if an experimenter's strategy is to vary two independent variables consecutively, in an attempt to answer a research question, then the experimental investigation is more appropriately conceptualized as a related two-fold integrated operation, not two unrelated events, as implied by Udolf and Raymond (1973). The error rate for the complete experimental investigation would be a function of the two related one-at-a-time subexperiments and would not differ from the error rate for two concurrent multiple F tests. Udolf and Raymond's (1973) recommendation of substituting multiple miniexperiments for an omnibus factorial design is indicative of their misrepresentation of the causative component of the problem; that is, alpha protection levels are effected by *any* multiple testing schema, not by complex factorial designs per se.

Instead of suggesting a solution that is untenable for the problem, Udolf and Raymond (1973) could have referred to the Bonferroni procedure, which is a viable solution for controlling the probability of a Type I error when computing many tests of significance (Games, 1971; Perlmuter & Myers, 1973).

The rationale of the Bonferroni procedure is to set a Type I probability risk for each test of significance so that the sum of the risks will not exceed the alpha protection level that the researcher wishes to maintain. For example, consider a two-variable design and its accompanying analysis of variance statistic in which there

is an F test associated with each treatment variable and the interaction of the treatment variables. If the experimenter wishes to maintain a .10 alpha protection level over all three tests, that is, over the experiment, then one means of partitioning alpha is to subject each F test to a .0333 (.10/3) level of significance and thereby control the overall alpha level at approximately .10. If the experimentwise error rate is to be evenly divided among the tests of significance, then Dunn (1961) has provided a table of critical values. The Bonferroni procedure, though, allows the experimenter to partition the Type I error to conform to his/her concerns regarding each test, just so the sum of the individual risks does not exceed the desired experimentwise error rate; e.g., .04, .04, and .02 could be used for testing the main and interaction effects, respectively, thereby maintaining a .10 overall protection level. As Perlmuter and Myers (1973) pointed out, the Bonferroni procedure is appropriate for any multiple testing situation in which the experimenter wants to control the probability of a Type I error.

Also, there are additional techniques that an experimenter may consider adopting instead of, or in conjunction with, the Bonferroni procedure, to protect the probability of committing a Type I error. Anderson (1968) noted that the experimentwise error rate can be controlled in multifactor paradigms by pooling sources of variation believed to be negligible. This pooling will reduce the number of hypotheses to be tested and hence aid in controlling the Type I error rate. Experimental design techniques can also be adopted to reduce the number of testable hypotheses. Incomplete designs, such as fractional factorials, enable the researcher to test a limited number of important hypotheses, with a frac-

tion of the number of subjects than would otherwise be required for a completely crossed design, by confounding some of the effects with higher order interactions (Kirk, 1968). Therefore, the number of hypotheses tested would be smaller than what would ordinarily be tested in a complete design, and the likelihood of a Type I error due to excessive multiple testing is diminished.

Either, or any combination, of the above three techniques would be appropriate strategies for controlling the Type I error rate for factorial experiments, while also permitting the researcher to benefit from the efficiency of factorial experimentation.

Further Thoughts on the National Board of Examiners in Psychology

Berg (November 1973) commented on my proposal (Coates, March 1973) for a National Board of Examiners in Psychology. It would be the task of this board to license all PhDs in psychology and, if there were an oversupply of candidates for certain jobs (e.g., teaching general experimental psychology), to limit the number of PhDs that were licensed. In other words, the passing score on the examinations administered by the National Board of Examiners in Psychology would be arbitrarily raised (or perhaps lowered) as a function of the number of candidates for different types of positions such as academic teaching, clinical, and industrial. The purpose of this comment is to respond to Berg's remarks.

First, Berg suggested that there is no need for a National Board of Examiners in Psychology because state licensing boards and mechanisms (unspecified) in use in universities and industry insure that adequate services are provided by psychologists. I reject this argument because it only concerns standards used *after* employment has begun. My proposal for a National Board of Examiners in Psychology concerns standards used *before* employment has begun.

Second, I agree with Berg that my proposal to arbitrarily limit the supply of PhD psychologists in the marketplace by raising the passing score on the examinations of the National Board of Examiners in Psychology is a little too Machiavellian in character. In other words, I no longer think that we should arbitrarily restrict the number of PhDs who can compete for jobs.

However, I still think that the National Board of Examiners in Psychology is a good idea. It seems to me that it could serve the useful function of providing national standards and examinations for licensing the PhD in psychology. I am not at all satisfied that a PhD has acceptable credentials when he/she has

taken courses in one department with perhaps 25-30 psychologists on the faculty and has completed a PhD thesis with 4-5 psychologists on his/her committee. With such a few psychologists to evaluate a candidate's performance, it is all too possible that factors such as an ingratiating manner, a long time in the program, and a desire to not hurt the feelings of the candidate or the candidate's adviser may serve as mitigating circumstances that allow a slipshod candidate to obtain a PhD in psychology. Thus, I continue to propose that a National Board of Examiners in Psychology be established.

Fourth, Berg stated that "it would be interesting to see who would sit on this (NBEP) board, and what criteria the board would use in arriving at its eligibility list." I reject this argument. It should be no more difficult to establish a set of examinations and standards than it currently is for lawyers for the bar examination; for physicians for the licensing examinations; for psychologists for awarding the diploma in clinical, school, and industrial psychology through the American Board of Professional Psychologists; or for psychologists and others who prepare the Graduate Record Examinations. Are psychologists such a diverse and divided group that they could not establish a set of examinations? I think not.

To decrease the rancor that may occur among psychologists in setting up examinations to be administered by the National Board of Examiners in Psychology, I suggest that an examination committee be established for each division of the American Psychological Association by a vote of the members of the divisions. Or, perhaps elections could be held in such broad areas as academic psychology, clinical psychology, and industrial psychology.

On "Salvation and Its Vicissitudes"

Beit-Hallahmi's (February 1974) article appropriately challenged the assumptions of clinical psychology. I tend, however, to react to his thesis as I react to other similar positions (e.g., Ryan, 1969, 1971), that is, by questioning whether if we focused primarily on social systems we would continue to be psychologists as usually defined. Wouldn't we instead be ill-trained sociologists, economists, political scientists, and/or social activists? If, as Hebb (February 1974) asserted, "what psychology is about" is the mind, we would surely be off base if we departed radically from the "emphasis on individual responsibility, internal causation, and individual solution to problems [p. 126]" which Beit-Hallahmi disparaged.

I will not argue with the point that our social systems are imperfect and in need of major modification if not complete overhaul. I do doubt that psychologists, clinical or otherwise, can make their best contribution as social mechanics. The assertion that our social systems profoundly affect the minds and behavior—perceptions, attitudes, cognitions, defenses, coping capacities, adjustments, mental health, mental illness, or whatever our interest—of our clients or patients is incontestable (Sarason, 1974, chap. 5). How shall psychologists function to be true to these facts and to the individual focus which has been the definitive and unique contribution of our discipline?

It certainly would not be original to suggest that we are or should be the experts at the interactions: interactions between biological predispositions and environmental forces, between instincts and learning (Hebb, 1974), between individual minds and

dispositions on the one hand and social institutions and influences on the other. Such a focus, or focuses, would employ our traditional methodology, data, and expertise, but would also provide sound bases for our recognizing environmental/social/institutional deficiencies and for working in our individual and corporate ways toward appropriate social remediations. Perhaps this is what Beit-Hallahmi had in mind, but I think it would be a mistake if, just as *mind* is being restored to the mainstream of our discipline, psychology should give way to a new radical environmentalism and become merely a social science.

Up with Our Foremother

Bernstein and Russo (February 1974) are to be commended for pointing out the contributions of women to psychology. It was a disappointment, however, that the earliest fighter for the place of women in psychology was omitted from the discussion. I refer, of course, to Mary Whiton Calkins (1863-1930), who began at the turn of the century to make her way in a male-dominated American psychology.

Ms. Calkins was a graduate student of William James, Hugo Munsterberg, and Josiah Royce at Harvard. Though she completed all doctoral requirements with distinc-

tion, Harvard's policy did not permit her, a female, to receive a degree (nor would she accept a PhD offered by Radcliffe in recompense). Nevertheless, Mary went on to establish a psychological laboratory at Wellesley College—the first such laboratory at a women's college—and to publish widely in the fields of psychology and philosophy.

Her major contributions to psychology were the *method of paired associates* and her *self-psychology*.

In 1905 Mary Calkins became the fourteenth president of the American Psychological Association, the first woman to hold this position. In later years she was elected an honorary member of the British Psychological Association.

Although well honored in her own lifetime, Mary Calkins has not been given her rightful place in the history of psychology. The times are ready to look again at Mary Calkins not only in recognition of her work in the field of psychology but also in recognition of her early demonstration and conviction that women have a rightful place in scientific and academic endeavors.

A Note in Support of Tyler on Elitism

In her Presidential Address at the APA convention, Tyler (December 1973) made some interesting comments on elitism that were encourag-

ing to this author. The following is an offering of some thoughts on the same issue. My hope is that these ideas will help in the effort to establish this topic as an important one that deserves continuing exploration.

The potential for elitist exploitation is inherent in the very nature of psychology. We, as psychologists, have taken on the task of trying to understand human nature in a detached sort of way. Along with other areas of study and artistic expression, our activity constitutes a kind of cultural introspection. The culture grants us the privilege of invading its privacy in the hope that the results of our probing will be beneficial to everyone. This is a mutual trust, and a delicate one, for simple reasons.

From the point of view of psychology and psychologists, the temptation to use this privilege mainly for personal and institutional self-enhancement is a great one. From the point of view of the culture, the temptation to use psychology to develop short-term expedient solutions to painful problems is equally great. The maintenance of this delicate trust requires thoughtfulness and sensitivity; we have been lacking in both.

In an effort to legitimize our work, we have tried to model psychology after the physical sciences, in which the scientist must prove his knowledge by demonstrating his control over the objects and events that he studies. The culture, in its naive worship of science, has amply rewarded psychologists for their scientific legitimacy. We have aspired to and we have been placed in a fundamentally elitist position.

Not only has psychology as an institution been rewarded with scientific legitimacy but in recent years the field has become potentially lucrative for *individual* psychologists. As more and more aspects of human living become institutionalized, individuals become less resourceful and more dependent on "experts." The public has thus become increasingly willing to reward psychologists with

money and social status in return for descriptions of, and advice about, human behavior.

From an ethical point of view, such caretaker relationships are a tight-rope that can be broken unwittingly at either end. How is it possible to know when each side of such a relationship is meeting its responsibilities, giving as much as it takes? How is it possible to know when the adviser's efforts are self-serving, keeping the advisee in an increasingly dependent position, so that monetary and social rewards will be increased in the future? On the other hand, is it not possible for the culture to abuse psychology? For instance, are we being prudent to acquiesce so readily in the face of current pressures for applied research? Is it not possible that profound social problems that have been in the making for centuries will refuse to yield to a decade or two of behavioral inquiry and intervention? What will be the fate of psychology should such a failure occur? As we strive to understand the ethical problems of our discipline, it should become clear that elitism is at the center of these problems.

And elitism could destroy us. As we seek and accept more remuneration for our psychological wares, we will create a greater need for them. Increasingly we will be called on to meet demands that are far beyond us. When this happens it will become clear that the mutual confidence of the culture and the profession has been violated, and both sides will suffer greatly.

To help maintain this mutual confidence, Tyler recommended that we be more thoughtful about planning our research directions and making our knowledge available to the general public; that we keep in mind the needs of psychology as an organized body of knowledge, the needs of our subjects and collaborators, and the needs of society. I would add to this program: We need to establish the exploration of ethical issues as a fully acceptable and fully supportable (i.e., financially) aspect of our pro-

fessional activity and as a required part of both undergraduate and graduate training in psychology.

Edgington's Tabulation of Statistical Procedures

In interpreting his tabulation of statistical procedures used in APA journals during 1964-1972, Edgington (January 1974) argued that statistics courses and texts should not fail to cover the procedures and methods used most often in psychological research. For example, he suggested that the analysis of variance for repeated measures and factorial designs are prime candidates for inclusion because they were used in 88% of the articles employing the analysis of variance, which in turn was used in 71% of the articles tabulated for 1972.

Certainly most psychologists would not disagree with the view that statistical training should be relevant to the needs of the users. However, I am concerned that Edgington's recommendations might be taken too literally or, worse yet, overgeneralized. Perhaps unintentionally, Edgington has conveyed the impression that we should let current practices play a major role in deciding which topics to include in statistics courses and texts. In principle, this criterion could be applied to both undergraduate and graduate situations, allowing for more extensive coverage at the graduate level. At the extreme, strict adherence to the criterion could produce a "vicious circle"; the statistical skills of each new generation of psychologists would not differ significantly (no pun intended) from the previous generation.

If we follow Edgington's tabulation, most of the training would be

NOTICE TO AFA AUTHORS

The American Psychological Association announces publication of the second edition of the *Publication Manual* in August 1974. This new edition, which supersedes the 1969 Manual, will be adopted by the 14 APA journals in 1975.

The new Manual is more comprehensive than the previous edition. It updates AIA publication policies and procedures and incorporates changes in editorial practice since 1967. For instance, AIA now sends many authors their copy edited manuscripts for review before they are set into type, and some editors now use blind review procedures. The second edition also includes up-to-date statements of the coverage of each AIA journal including the *Journal of Experimental Psychology* which will be published in four separate sections in 1975.

The new *Endocrine Manual* initiates several changes in AFA style. These changes are announced in the August 1974 *American Physiologist* and will be introduced in the AFA journals in January 1975. During the period of transition to the new style, authors should note that (a) all manuscripts published in 1974 will be copy edited according to the 1967 Manual, (b) manuscripts accepted in 1974 and published in 1975 will be copy edited to conform to the new Manual starting in 1975, accepted manuscripts that depart significantly from the Manual will be returned to authors for correction.

Authors will be encouraged by the changes in the second edition. The new AHA style simplifies reference forms, eliminates unnecessary underlines, brackets, and other devices, requires appropriate use of 1 and 2, and generally clarifies typing requirements. Material is arranged for maximum convenience to authors and typists and all systems are completely revised.

The new *Index* and *Manual* is available after August 1 for \$1. Send orders to AHA Publication Sales, 1700 Connecticut Avenue, N.W., Washington, D.C. 20009. Orders of \$10 or less must be paid in advance unless they are submitted on institutional purchase order forms.

What's always the same? but never the same?

Human behavior. You and your colleagues are finding many ways to interpret it, yet you never quite interpret it all. The real question is how you can keep up with pertinent topics in psychology. The answer: books from John Wiley.

1. DRUGS AND BEHAVIOR A Primer in Neuropsychopharmacology

By Ernest L. Abel,
New York State Dept. of Mental Hygiene

For graduate and undergraduate students in the social and medical sciences, this book clearly outlines the nature of drug action beginning with the absorption of drugs into the body and ending with their elimination. It discusses the various factors influencing this process from the context of the nervous system and drug-receptor theory. 1974 256 pages \$13.95

2. ORIGINS OF FEAR, Volume 2

Edited by Michael Lewis, *Educational Testing Service*, and Leonard A. Rosenblum, *State University of New York Downstate Medical Center*

Showing how fear represents the conflux between the infant's emerging cognitive and affective systems, this book provides both ontogenetic and phylogenetic perspectives. Its chapters reflect the integration of original papers, critical comments, and thematic discussions from a conference on fear, supported by the Educational Testing Service, Princeton, New Jersey. Topics include Fear-Mediated Processes in the Context of Imprinting • Fear and the Development of Social Attachments in the First Year of Life • Self, Other, and Fear: Infants' Reactions to People • and more.

A volume in the Wiley Series on the Origins of Behavior, edited by Michael Lewis and Leonard A. Rosenblum 1974 approx. 384 pages \$14.95 (tent.)

3. THE ARTS AND HUMAN DEVELOPMENT A Psychological Study of the Artistic Process

By Howard Gardner, *Harvard University*

"Howard Gardner's *The Arts and Human Development* has that special quality of appreciating mysteries in the nature of art, while at the same time looking coolly and technically at the component skills involved in producing and viewing art. It is a penetrating book."—Jerome Bruner

University of Oxford 1973 395 pages \$14.25

The following are volumes in the Wiley Series on Personality Processes, edited by Irving B. Weiner

4. THE VOLUNTEER SUBJECT

By Robert Rosenthal, *Harvard University*, and Ralph L. Rosnow, *Temple University*

A comprehensive review of literature on the employment of volunteer subjects in behavior and social research, this book emphasizes the characteristics of those who volunteer, draws causal inferences from the implications of these characteristics, and assesses situational determinants of volunteering and procedures for increasing external validity. 1974 approx. 288 pages \$13.95 (tent.)

5. INNOVATIONS IN CLIENT-CENTERED THERAPY

Edited by David A. Wexler, *University of California*, and Laura North Rice, *York University, Ontario*

This volume of original papers provides an in-depth view of new developments in client-centered therapy. It gives readers a detailed picture of contemporary theory and practice in client-centered thought. Beyond the theory and practice of individual psychotherapy, the book emphasizes the extension of client-centered thinking to a broader social context—showing readers how its principles can be used in society to promote change both in the individual and in his social environment. 1974 approx. 425 pages \$22.50

CHARLES C THOMAS • PUBLISHER

PRESCRIPTIONS FOR CHILDREN WITH LEARNING AND ADJUSTMENT PROBLEMS (2nd Ptg.) by Ralph F. Blanco, *Temple Univ., Philadelphia, Pennsylvania*. Emphasis in this book is given to learning and behavior problems in school and at home. Concepts are derived from psychodynamic, reinforcement and need theory orientations. Techniques, curricular suggestions and remedial ideas are given for withdrawn and aggressive behaviors such as stealing and negativism, suicidal and homicidal behaviors, passive-aggressive behavior, underachievement and school phobia. Also discussed are the blind, deaf and brain injured, retardation, the slow learner and learning disabilities. Recommendations are given for classroom and home management, rivalry and anxiety. '74, 320 pp., \$9.25

PSYCHO-MOTOR BEHAVIOR IN EDUCATION AND SPORT: Selected Papers by Bryant J. Cratty, *Univ. of California, Los Angeles*. This text contains papers delivered on a variety of topics relating psychomotor activity to both the athletic science and the therapeutic strategies and programs. It includes discussions of visual-perceptual behaviors, the role movement plays in various educational programs and essays dealing with intelligence in movement education programs and athletics. Also included are a discussion of the clumsy child syndrome, a check list through which motor ineptitude in children may be assessed, development of the body image and movement in programs for handicapped children. The psychology of the superior athlete and criteria for evaluating the superior athlete are detailed. A comparison of the movement attributes of Chicano, Anglo and Black children is one of the featured research studies. '74, 190 pp., 5 il., \$9.75

OCCUPATIONAL STRESS. Edited by Alan McLean, *New York Hospital, White Plains, New York*. (78 Contributors) The term "stress" has different meanings within the many disciplines which use it. This book and the conference on which it is based present the most widely held concepts of occupational stress for the first time in a single volume. Theoretical concepts, research results and specific suggestions for coping with stress-related problems, however defined, are included. Psychiatric, psychoanalytic and psychophysiological considerations are discussed as are those which stem from role theory. The purpose of the book is to bring together the many concerned disciplines to present their points of view so that a picture of current thinking can be obtained and the various definitions of the term can be understood. '74, 128 pp., 21 il., 9 tables, \$9.75

THE PSYCHOLOGY OF LEISURE: Research Approaches to the Study of Leisure by John Neulinger, *City College of the City Univ. of New York*. This book was written with the purpose of restoring leisure to its rightful place and to show that man must have leisure in order to become oneself and be oneself. The book is addressed to those professionals in colleges and universities, in labor and management organizations and in public and private community agencies who are concerned with a formal education for leisure. It is also written for students of leisure in a broader sense, those whose professional interests bring them in contact with problems of leisure. Research approaches to the study of leisure are stressed and leisure is viewed from a psychological standpoint. The main goal of the book is to redefine leisure so that it can become the ultimate goal of our society. '74, 240 pp., 1 il., 14 tables, \$9.75

THE AMERICAN CONFIDENCE MAN by David W. Maurer, *Univ. of Louisville, Louisville, Kentucky*. The field work for this book was done by the author using well established techniques of anthropological, criminological and linguistic research. He has explored a large number of criminal subcultures including thieves, gamblers, forgers, counterfeiters, criminal narcotic addicts and other professional criminals both in this country and abroad. The book explores such questions as how professional status is acquired, how a criminal maintains his reputation in his own culture and how that culture differs from the dominant culture. The status of women, the establishment of families and the raising of children are discussed. Attitudes of the criminal subculture, protection, money and valuables, recreation and religion are also included. '74, 316 pp., cloth-\$11.75, paper-\$6.95

GROUP COUNSELING AND THERAPY TECHNIQUES IN SPECIAL SETTINGS. Edited by Richard E. Hardy, *Virginia Commonwealth Univ., Richmond*, and John G. Cull, *Virginia Commonwealth Univ., Fishersville*. The book offers material on group counseling with adolescents in the school setting, with the disadvantaged, with people who are mentally handicapped and with public offenders. Two group methods are described for use with the severely disabled individual, marital counseling in groups, behavioral group therapy with alcoholic abusers and group work through peer pressure. The book concludes with the use of group counseling in achieving adjustment to work. The purpose of this book is to pinpoint settings and describe the techniques and approaches in a practical style. '74, 180 pp., 3 tables, \$10.75

DEPRESSION

causes
and
treatment

Aaron T. Beck, M.D.

Interestingly written, highly informative, well documented, and of high scientific quality. . . . It makes an important contribution to the psychology of depression. . . . Since depression is a treatable disorder, and one whose diagnosis is not always clear, this is a book which should be read by every medical student and psychiatric resident as well as by psychiatrists already in practice.

—John M. Davis, M.D., *American Journal of Psychiatry*

Appraisals of this breadth are hard to find. It will be valuable to research workers and clinicians alike, and it well deserves recognition as a classic text.

—*British Journal of Social and Clinical Psychology*

This volume without doubt transcends all previous writings on depression.

—*International Journal of Group Psychotherapy*

Now available in a paperback edition for students at only \$4.45!

Also available in cloth: \$12.50.

A publication of the University of Pennsylvania Press.

This is a most valuable book which, in readable style, has developed an excellent overview of the syndrome.

—*Psychiatry Digest*

It is well-written, clear, free of jargon, and interesting. His ambitious efforts have made it the most impressive recent work on depression.

—*Annals of Internal Medicine*

Can be characterized by the most positive adjectives one might think of in evaluating a book in medicine or psychiatry.

—*Bulletin of Suicidology*

A welcome addition to the clinician's library and a reference source for graduate students studying psychopathology.

—*Contemporary Psychology*

A most stimulating and useful text.

—*Psychosomatic Medicine*

The principal work on the subject and a valuable source of reference.

—J. R. M. Copeland, M.D., *British Journal of Psychiatry*

Excellent and much needed study of depression, which will be particularly useful to students of abnormal psychology in university departments, and also to clinical psychologists.

—*British Journal of Psychology*

The best book I know of on the subject, with the right mixture of the psychiatric and psychological approaches.

—Paul E. Meehl, Ph.D., *University of Minnesota*

I have found Dr. Beck's book extremely useful in classes and extremely useful in connection with research in this field because of its encyclopedic nature.

—Joseph Zubin, Ph.D.

Undoubtedly the most comprehensive, sophisticated and original work on depression that has appeared in years . . . Beck's contribution is to add a new dimension to the psychodynamics of depression. His book introduces a radical shift of focus . . . to the cognitive organization underlying self-esteem and depression. . . . It amply lives up to the promise of comprehensiveness contained in its title.

—Myer Mendelson, M.D., *Psychiatry and Social Science Book Review*

SOCIAL PSYCHOLOGY

Issues and Insights/2nd edition

GOODWIN WATSON, *Columbia University*, and DAVID W. JOHNSON, *University of Minnesota*

This edition offers increased emphasis on the application of social psychological knowledge to the solution of current social problems, and will appeal to instructors who seek a current alternative to texts that principally stress theory and research. Approximately half the material in this edition is new. *Instructor's Manual*.

475 pages/1972/paperbound \$7.75

CONTEMPORARY SOCIAL PSYCHOLOGY

Edited by DAVID W. JOHNSON, *University of Minnesota*

The editor seeks to demonstrate that well-validated social psychological theory can be applied effectively to the solution of social problems and improvement of interpersonal relationships. Consisting of introductory essays by the editor and a selection of appropriate articles, the book progresses from a definition of humanistic social psychology to discussions of self-actualizing relationships, and relationships between individuals, organizations and society.

479 pages/1973/paperbound \$6.75

BEHAVIOR DISORDERS

Perspectives and Trends/3rd edition

OHMER MILTON and ROBERT G. WAHLER, *University of Tennessee*

The editors have completed a major revision of this outstanding collection of readings. Divided into three sections, The Medical Model, Situational Influences, and Alteration of Behavior, nineteen articles—sixteen new to this edition—provide students with an overview of current thinking and the results of recent psychosocial research on abnormal behavior.

326 pages/1973/paperbound \$5.75

DIMENSIONS OF PSYCHOLOGY

Introductory Readings

Edited by GALE B. BISHOP, *University of Albuquerque*, and WINFRED F. HILL, *Northwestern University*

The editors have selected forty-four articles especially for their capacity to communicate significant research at a level understandable to most college students. The contributors represent a cross-section of researchers, and the selections include material on such relevant topics as drug abuse, mental health and violence.

480 pages/1972/paperbound \$5.95

THE GREAT PSYCHOLOGISTS

3rd edition

ROBERT I. WATSON, *University of New Hampshire*

Professor Watson reviews the lives and works of the principal architects of today's science of psychology from its origins in the thought of pre-Socratic Greeks. Substantially rewritten for added clarity, the book is now available in paperback.

627 pages/1971/paperbound \$7.50

SEX and the INTELLIGENT WOMAN

MANFRED F. DeMARTINO

With a concluding chapter by Albert Ellis

Is high intelligence in woman compatible with an active and enjoyable sex life? The question has particular relevance today as the conventional image of woman gives way to a broader view of women's mental powers and right to personal fulfillment. Nearly 300 women members of MENSA here answer in their own words the author's detailed questionnaire on their sexual practices and attitudes, and their replies are correlated to Maslow's personality scale. In a closing chapter, Dr. Ellis relates the findings to his own and other research studies and places them in the cultural context of modern society.

Just published, 320 pp., \$8.95

BIRTH CONTROL and UNMARRIED YOUNG WOMEN

CONSTANCE LINDEMANN

What do sexually active, unmarried young women and adolescents do about birth control, and why, if they want to avoid pregnancy, do they not use contraceptives? The answer is authoritatively presented in this book based on Dr. Lindemann's research at UCLA's School of Public Health. From a prescription for preventing pregnancy to the theory of the birth control prescription process, it offers behavioral scientists and therapists sound, needed information.

THE NATURAL MIND

A New Way of Looking at Drugs and the Higher Consciousness

by **ANDREW WEIL**. "... his deep understanding of the dynamics and principles of consciousness enable him to look at this problem from a very new and refreshing point of view."—ALAN WATTS \$2.95

THE BOOK OF FAMILY THERAPY

by **FERBER, MENDELSON and NAPIER**. The couples who choose to "suffer it out in silence," while inevitably the tension and unhappiness pass to their children, are the focus of attention in this study which will inspire those interested, or already working, in family therapy. \$4.95

NIGHTMARES AND HUMAN CONFLICT

by **JOHN E. MACK, M.D.** An attempt to understand the nightmare as a unique but universal experience which almost always involves conflicts with which the dreamer feels powerless to cope. \$3.45

THE PSYCHOLOGY OF ANOMALOUS EXPERIENCE

by **GRAHAM REED**. Considers unusual and puzzling experiences—*déjà vu*, illusions, hallucinations, etc.—in terms of errors in our normal psychological processes of gathering, monitoring, processing and storing information about the world around us. \$3.95

WIZARD OF THE UPPER AMAZON

by **F. BRUCE LAMB**. Introduction by **ANDREW WEIL**. The incredible seven-year adventure of Manuel Córdova-Rios, a young Peruvian, who after his capture by Amazon Indians was trained to be their chief and was taught the ways of the tribe and jungle through the use of an hallucinatory extract from the "vision vine." Córdova-Rios is now a well-known healer in Peru. \$2.95

THE BEGINNINGS OF MODERN AMERICAN PSYCHIATRY

The Ideas of Harry Stack Sullivan by **PATRICK MULLANEY**. As early as 1925 Sullivan came to regard interpersonal relations as paramount in the etiology of mental illness, maintaining that intrapsychic processes could not be separated from the social history and current living of the individual. \$4.95

ON BECOMING A PERSON

by **CARL ROGERS**. This classic work challenges many concepts and attitudes of traditional psychology and poses such fundamental questions as: What is personal growth and under what conditions is it possible? How can one person help another? What is creativity and how can it be fostered? \$4.95

"A thoughtful, original, and systematic contribution."

Theodore Newcomb, University of Michigan

The Evolutionary Foundations of Psychology

A UNIFIED THEORY

by **FELIX E. GOODSON**

The author begins with primitive life and the environmental context in which it must have evolved. From this examination he derives the fundamental postulates of the theory which are then extended to subsume and integrate much of the traditional subject matter of psychology. The book traces the evolutionary emergence and adaptive function of the psychological attributes of man, including sensation, perception, the self concept, learning, attention, thinking, and abnormal behavior. The author presents a comprehensive, unified conceptual system which gives a naturalistic view of man as a product of evolution.

"The basic ideas are unusually provocative and make a real contribution to psychological thought. A unique feature is the concrete utilization of evolutionary thinking."

Melvin Marx, University of Missouri

"I would like to assign it to all majors in psychology."

Carroll Pratt, Princeton University

Every psychologist should read this important new book. In addition, you should consider adopting Goodson's book if you teach advanced general, comparative or any course which covers theories of psychology and if you want to expose students to a contemporary, integrative system based on evolutionary theory.

240 pages, \$8.00

Send for a 10 day approval copy or if you include payment, we will pay postage and handling. Price subject to change without notice. Please address inquiries to Cliff Snyder, Consumer Sales, HOLT, RINEHART AND WINSTON, INC. 383 Madison Avenue, New York 10017

»FROM ONE TO FOUR«

APA announces the reformatting of the **JOURNAL OF EXPERIMENTAL PSYCHOLOGY (JEP)**. Effective January 1975, the **JOURNAL** will be published as four independently edited and distributed sections. The broader editorial focus is intended to provide a mechanism for more integrative reports of general experimental research as well as the usual articles dealing with specialized areas of experimental psychology. The **Journal's** four sections are:

☐ **JEP: General.** Comprehensive and integrative reports of new research leading to a substantial advance in knowledge which are of interest to the entire community of experimental psychologists. Four issues published March, June, September, and December. \$6 to APA members only.

☐ **JEP: Human Learning and Memory.** Experimental studies on fundamental acquisition, retention, and transfer processes in human behavior. Six issues published January, March, May, July, September, and November. \$10 to APA members only.

☐ **JEP: Human Perception and Performance.** Experimental studies designed to foster understanding of information-processing operations and their relation to experience and performance. Four issues published February, May, August, and November. \$6 to APA members only.

☐ **JEP: Animal Behavior Processes.** Experimental studies concerning the basic mechanisms of perception, learning, motivation, and performance, especially as revealed in the behavior of infrahuman animals. **NOTE:** Animal experimental studies, formerly published in the *Journal of Comparative and Physiological Psychology*, have been reinstated as a major component of **JEP**. Four issues published January, April, July, and October. \$6 to APA members only.

■ **SPECIAL ORDERING INSTRUCTIONS:** APA members may subscribe singly, in self-selected combinations, or to all four sections for \$25 per year. Institutions and nonmembers must subscribe to all four sections at \$60 (Foreign \$61) per year. To order your subscription, please send your request accompanied by full payment or institutional purchase order to:

American Psychological Association
Subscription Department
1200 17th Street, N.W.
Washington, D. C. 20036

Please note that all subscriptions must be prepaid except for those submitted on institutional purchase order forms. Subscriptions to **JEP** are on a calendar-year (January through December) basis only. Subscriptions entered during the year receive back issues for that year.

OUTSTANDING TEXTBOOKS

BEHAVIOR THERAPY: TECHNIQUES AND EMPIRICAL FINDINGS

DAVID C. RIMM, Southern Illinois University
JOHN C. MASTERS, University of Minnesota

A comprehensive presentation of existing behavior therapy techniques which stresses practical applications while making extensive use of case histories and controlled experiments.

"One of the most well written, concise and highly organized books in a field that has already produced some outstanding books. Rimm and Masters have finally come up with a book in which there is parity between theory, research, and practical application."

—Bijan Guilani, University of California at Los Angeles

"Superb! A long overdue and well balanced presentation."

—M. J. Mahoney, Pennsylvania State University

513 pages \$11.95

PSYCHOLOGY OF VERBAL LEARNING AND MEMORY

DONALD H. KAUSLER,
University of Missouri

A thorough review of the field which investigates the theoretical and empirical issues in terms of both their historical development and their contemporary status. Verbal learning is approached from the perspectives of both S-R associationism and information processing. Each topic is supported by a systematic, critical analysis of the underlying processes, the functional relationships between these processes, and the important independent variables.

583 pages \$12.95

INTRODUCTORY STATISTICS FOR THE BEHAVIORAL SCIENCES

JOAN WELKOWITZ, ROBERT EWEN,
and JACOB COHEN,
all at New York University

Users of this text unanimously praise the simplicity and clarity with which sophisticated concepts are presented to beginning students. The material is developed in a logical, coherent, and interesting fashion, with the objective that students obtain an understanding of both what they are doing and why they are doing it.

271 pages \$8.95

WORKBOOK by ROBERT EWEN
155 pages \$2.95

A PRIMER OF MULTIVARIATE STATISTICS

RICHARD J. HARRIS,
University of New Mexico

Emphasizing the use of techniques rather than their derivation, this new text provides a practical introduction to the field for students in the behavioral and social sciences. Designed for students who have a minimal mathematics background, no prior knowledge of matrix algebra or calculus is assumed. Numerous demonstration problems provide simplified illustrations of important techniques and enable the student to fully explore their heuristic properties.

Ready December 1974, about 356 pages,
probable price \$13.95

A HISTORY OF MODERN PSYCHOLOGY

Second Edition

DUANE P. SCHULTZ,
American University

Class tested and revised to reflect feedback from instructors and students, the new second edition maintains Professor Schultz's distinguished approach to the history of modern psychology while incorporating significant new material.

- Expanded coverage of humanistic psychology
- Greater emphasis on the spirit of mechanism
- New material on the lives and works of individuals
- Greatly expanded discussion of B. F. Skinner
- New original source material

Ready January 1975, about 400 pages,
probable price \$9.95

WHERE DO YOU DRAW THE LINE?

Where is the line between art and pornography? What kind of violence is in the media? What are the legal and ethical boundaries of research? Amendment?

These are a few of the tough, thorny questions that are faced head-on in this book, which includes opinions from such prominent writers as Alexander Bickel, Robert Fitch, Irving Kristol, Roscoe Pound, Hans J. Morgenthau, Norman Mailer, Albert J. Segal, Fredric Wertham, and 12 more.

Together, they supply one of the most important and provocative studies on pornography, media violence, and censorship in decades since the 1952 law passed.

Thesaurus of Psychological Index Terms

Contains over 4,000 terms representing an authoritative, unambiguous, and hierarchically structured vocabulary used by psychology and related disciplines. This vocabulary will facilitate precise content representation of concepts described in psychological literature and allow for more flexibility in automated search and retrieval operations. These two factors promote more effective communication of psychological concepts in original works and research, ultimately aiding the content of publications to be focused in accordance with the interest patterns of psychologists.

This **Thesaurus**, developed by the Psychological Abstracts Information Services, is divided into three sections:

The **relationship** section shows the relationships among concepts that are associated with each other. Term relationships noted are synonymous, broader, narrower, or related.

The **alphabetical** section presents each preferred term in alphabetical order, enabling rapid identification of terms used for indexing.

The **hierarchical** section contains 17 broad content areas in which terms are presented in descending order according to breadth of concept represented. The 17 categories correspond to major classifications used in *Psychological Abstracts*.

The **relationship**, **alphabetical**, and **hierarchical** sections will assist the user in selecting appropriate terms for different uses.

Administrators

- determine areas of research for an organization
- assure representative expertise in personnel selection

Researchers and Authors

- find synonyms for a term representing a concept
- select terms that represent a concept
- define subject matter topics for a paper or book

Educators

- structure a curriculum
- use as a tutorial aid

Consultants

- search the literature
- aid in retrieval of information

Librarians

- provide access to psychological literature
- aid in cataloging psychology material
- aid in ordering new psychological literature

Students

- locate concepts relevant to psychology
- focus areas of study

The **Thesaurus** contains 382 pages with a hard cover and costs \$12. Please note that all orders amounting to \$15 or less must be accompanied by full payment except for those orders submitted on institutional purchase order forms.

**NEW
FROM CALIFORNIA**

**Alphabetic and Phonemic
Texts of Informal Speech
with Statistical Analysis**
Edward C. Carterette
& Margaret Hubbard Jones

It has long been known that informal spoken language is significantly different from written language. The extent of the difference, however, has never been fully appreciated because of the lack of information on the spoken language. The present work attempts to fill this gap by providing a careful description and quantification of "standard" spoken language. The authors draw several important conclusions from their analyses of the running dialogs of peer groups of persons in free discussions.

646 pages \$21.00

**The Economy of Nature
and the Evolution of Sex**
Michael T. Ghiselin

This book seeks to develop a Darwinian, non-teleological view of the "natural economy," after a *laissez-faire* model rather than the traditional cooperative ideal. Dr. Ghiselin reviews a variety of theoretical topics, most of which concern the evolutionary interpretation of sex and other reproductive phenomena. The author challenges the validity of purely theoretical systems and emphasizes empirical evidence, offering a large body of factual material on "reproductive strategies" in the plant and animal kingdoms.

BERKELEY 94720

**The 1st Annual TEMPLE CONFERENCE
on BEHAVIOR THERAPY AND BEHAVIOR
MODIFICATION: 50 Years of Progress**
November 14-17, 1974

Lectures and workshops at introductory and advanced levels. Sponsored by the Behavior Therapy Unit, Department of Psychiatry, Temple University School of Medicine. Partial list of lecturers and workshop leaders:

Teodoro Ayllon, L. Michael Ascher, Nathan Azrin, Donald Baer, David Barlow, John P. Brady, Paula Bram, Joseph R. Cautela, Edna Foa, Martin Gittelman, Israel Goldiamond, Alan Goldstein, Michael Hersen, Mary Cover Jones, Ogden Lindsley, Richard W. Malott, Neil E. Miller, Peter Nathan, Debora Phillips, Leo J. Reyna, Thomas Stampfl, Johann Stoyva, Joseph Wolpe.

FEES: Pre-registration: \$35.00 (\$40.00 after Oct. 20, 1974) for the general sessions. There will be an additional fee for workshops and conversation hours. The number of participants for each workshop and the conversation hour will be limited. For additional information please write or call: Dr. Edna Foa, Behavior Therapy Unit, Temple Department of Psychiatry, Room 706, Care of EPPI, Henry Avenue and Abbottsford Road, Philadelphia, Pa. 19129. Phone number is 215-GE8-4298, X 54.

**Keller's Personalized
System of Instruction:
An Appraisal**

Bruce A. Ryan, author; *Foreword* by Fred S. Keller. Offers the reader an objective assessment of the relevance of behavior theory, the role of unit tests, the appropriateness of the student proctor, and the success of self-evaluation in this increasingly popular approach to college-level education. In addition to an analytical review of the current literature, future directions for PSI are proposed and an invaluable "how-to" bibliography is included. 1974. 32 pp. \$2.

PSYCHOLOGY: AN INTRODUCTION

SECOND EDITION

JEROME KAGAN, *Harvard University*

ERNEST HAVEMANN

*The leading
brief introductory textbook because...*

"It does just about everything well. . . . The book covers all the traditional subject areas of introductory psychology, but it also includes the application of that subject matter in the everyday lives of its readers. Starting with an early emphasis on learning, the authors make very effective use of photographs, drawings, and cartoons, and they use a writing style that will catch and maintain student interest. An excellent text."

—Richard A. Kasschau, in *Contemporary Psychology*, 1973, Vol. 18, No. 12

"Beyond the accuracy of content, the book has one critical positive attribute. Students READ it!"

—W. M. Frankhouser, Jr., Pennsylvania State University

"Kagan and Havemann have done an outstanding job of presenting technical facts in a very readable manner. Students like it!"

—Delbert J. Sompeon, University of Evansville

"The combination of a Harvard psychologist and a professional writer is hard to beat."

—L. W. Williams, Pacific Union College

"The book is the perfect answer to both educating and motivating students of varying levels of ability and interest."

—Ola Barnett, Pepperdine University

Accompanied by an INSTRUCTOR'S MANUAL, STUDY GUIDE WITH PROGRAMED UNITS, three TEST ITEM FILES, and A GUIDE FOR INSTRUCTORS: BACKGROUND AND LEARNING OBJECTIVES.
584 text pages. \$11.95

Nonverbal Communication Readings with Commentary

Edited by SHIRLEY WEITZ, The Graduate Faculty, New School for Social Research. "Weitz has put together an excellent set of readings, and has organized them in a fashion that is simultaneously sensible and instructive. The readings themselves represent distinctively modern approaches to their subject matter and all make useful contributions."—Keith H. Basso, University of Arizona. "Best collection of articles on the topic to date."—Randolph M. Lee, Trinity College, Connecticut

1974 368 pp. 18 photos; 40 line drawings cloth \$10.00 paper \$4.95

Sight and Mind

An Introduction to Visual Perception

LLOYD KAUFMAN, New York University. "This is a remarkable book. It is both broad and deep, a combination of qualities seldom achieved; it is a textbook of ideas as well as a source of necessary detail."—Julian Hochberg, Columbia University. "Really excellent, should pretty well take over as 'the' perception textbook. Also good as an advanced, extensively referenced piece of scholarship. Rare combination."—William N. Hayes, Albion College, Michigan

1974 560 pp. 258 illus. \$14.95

The Psychologists

Volume II

Edited by T. S. KRAWIEC, Skidmore College. Eleven distinguished psychologists describe their intellectual life styles in these autobiographical essays. The essays reflect the personality, outlook and ideals of the scholars as they reveal the highly subjective spirit of their work and thinking. Contributors include: Heinz L. Ansbacher, Josef Brožek, Raymond B. Cattell, J. McVicker Hunt, Arthur R. Jensen, Howard H. Kendler, Robert Ward Leeper, Gardner Murphy, Charles E. Osgood, Carl Pfaffmann, and Morris S. Viteles.

1974 350 pp. 11 illus. cloth \$10.95 paper \$6.95

Children and Adolescents

Interpretive Essays on Jean Piaget
Second Edition

DAVID ELKIND, University of Rochester. "A highly readable and practical review of Piaget's ideas of importance to educators and psychologists."—Adam P. Matheny, Jr., University of Louisville. "Very good and needed since Piaget is at times difficult to put across to undergraduates."—Annette R. Hiedemann, West Virginia Wesleyan College. "The most readable book yet on Piaget."—Elias H. Wiebe, Pacific College

1974 208 pp. cloth \$6.95 paper \$2.95

A Handbook for the Study of Suicide

Edited by SEYMOUR PERLIN, Georgetown University. For a balanced consideration of suicidal behavior, this multidisciplinary text first approaches the subject from historical, literary, and philosophical points of view and then presents valuable material from the social sciences. The purpose is to analyze the contribution that each relevant discipline makes to the understanding of suicide. Eleven essays include contributions by such authors as George Rosen (history), A. Alvarez (literature), Solomon Synder (neurobiology), and Peter Sainsbury (community psychiatry).

Proven Competitor *for the* Introductory Course

Here's what instructors wrote us when they first looked at **The Psychology of Being Human** by Elton McNeil and adopted it for use this fall:

"It is a masterpiece in a deadly repetitive field of books, i.e., introductory psychology books."

"The finest introductory book I've seen to date."

"Excellent coverage and organization of contents."

The text is accompanied by a Study Guide, Test Bank and Instructor's Manual.

New this fall. . .

THE BETHLEHEM DIARIES: STUDENT-MENTAL PATIENT ENCOUNTERS

by Stuart Golann, Jay Pomerantz, Jeffrey Baker

This supplementary text for the abnormal psychology course provides case studies of state mental hospital patients, hospital records, patient interviews—all to bring into focus the world of mental illness and, more pointedly, the world of mental patients. Available in paperback, \$3.50t.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions. Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the Journal, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this Journal may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness. Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author and do not constitute APA policy unless so indicated. APA reserves the right to edit all copy and to refuse ads that are not in consonance with the principles of Title VII of the Civil Rights Act of 1964 (Equal Employment Opportunity).

Written permission must be obtained from the APA for copying or reprinting text of more than 500 words, tables, or figures. Address requests to the Permissions Office.

The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

Remember That Old Theory of Memory?

Well, Forget It!

JAMES J. JENKINS *University of Minnesota*¹

From the early 1950s until the early 1960s, Wallace Russell and I directed a project aimed at examining the role of language in behavior. While that project involved most of the staff of the psychology department at Minnesota at one time or another and concerned itself with everything from clinical protocols to nonsense syllables, the long-term, persisting core of the project turned out to be the studies that Russell and I performed with word associations. Here we examined the effects of established associations on learning, recall, recognition, perception, and problem solving. Everywhere we looked we seemed to find powerful relationships. Then we proceeded to establish associations *de novo* and repeated these studies with materials constructed entirely in the laboratory so we could control the histories of the associations that we were dealing with. (An account of these studies is given in Jenkins, 1963, 1970.)

Those were very exciting days for us. When the research program began, there was virtually no experimental evidence for mediation theory, although such a theory was widely applied in the analysis of higher mental processes (e.g., Osgood, 1953). By the time the program was over, media-

tional phenomena were well established, due in part to our efforts. When the program began, experimentalists (with a few exceptions like Cofer & Foley, 1942) regarded association norms as something belonging in the clinical domain. By the time the program was over, experimentalists were using norms for all kinds of materials as important ingredients in their investigations. But, on the other hand, when the research program began, we were hopeful that we could proceed directly from our experimental work to a general account of language itself. By the time the program was over, we were convinced that *that* particular journey was not possible.

So, in spite of the fact that the theory we espoused was gaining in popularity and in spite of the fact that we had produced a very large number of successful experiments (Russell and I had done about 120 studies and David S. Palermo and I had done about 40 or 50), we abandoned that line of research. The trouble was that we became convinced that the "higher mental processes" were not the kinds of things that we had originally believed them to be. In spite of the fact that we were moving rapidly, we were not going where we wanted to go.

As we struggled with this problem, I became convinced that I was caught in a metatheoretical trap, a trap that I had built for myself without ever realizing it. My friends and I were carrying about with us common sets of unexamined beliefs and attitudes that both directed and limited our research and theory in many ways. I will leave it to others to examine their own presuppositions; the following are the ones that I now see as dominant in my thinking in the 1950s:

1. *Units.* I believed that words were the fundamental units of language. To me this was natural and obvious.

¹ This article was the presidential address to Division 3, presented at the meeting of the American Psychological Association, Montreal, August 1973. Preparation of this article was supported in part by National Science Foundation Grant GB-35703X and National Institute of Child Health and Human Development Grant HD-01136 to the University of Minnesota Center for Research in Human Learning and by the Graduate School of the University of Minnesota.

In addition to the students and colleagues mentioned in the text, I would like to thank Robert Shaw, Walter Weimer, Robert Verbrugge, Nancy McCarrell, Jerry Wald, and Christine Bremer for their assistance. The central theme of the article, however, was derived from suggestions made by the late Richard M. Jenkins and it is to him that this article is dedicated.

Requests for reprints should be sent to James J. Jenkins, Department of Psychology, University of Minnesota, 205 Elliott Hall, Minneapolis, Minnesota 55455.

2. *Relations.* I believed that there was one kind of relation between words, associative linkage. Words became linked to each other through use together or use in the same "frames."

3. *Structures.* I believed that mental structures (if there really were any) were assemblies of links, essentially *chains* of the fundamental units in their fundamental relation. Hierarchies, like Hull's "habit family hierarchies," were simply lists of chains varying in strength, so that one was employed first, then another.

4. *Complex behaviors.* I believed that complex behaviors were built of simple subassemblies and that things got more complicated but *not* different "in kind." (This belief justified concern with simple units and relations and sanctioned experiments on such units in the faith that they would eventually add up to the complex behaviors of language.)

5. *Mechanistic explanation.* I believed that explanation ultimately rested on a description of the machinery that produced the behavior. I believed that a description of the machinery plus the history of the organism and its present circumstances inevitably predicted its behavior. There are two corollaries of this belief. First, I thought that the action of the machinery must necessarily be automatic. And, second, I could see that most of the interesting behaviors had to be explained by extensive reliance on learning and memory.

While these particular expressions of belief are probably unique to me, it is easy to see that they embrace the usual metatheoretical presuppositions that we identify with associationism. The associationist believes in some kind or kinds of basic units. (The number is not important.) He believes in some kind or kinds of relations between units. He holds that the more complex behaviors are the same "in kind" as simple behaviors. He believes that explanation consists of an explication of mechanism. He believes that behavior is automatic and for any kind of complex behavior, he relies on memory.

This view is so pervasive in American psychology that it is almost coextensive with being an experimentalist. Indeed, I think many of us confuse the dicta of associationism with the grounds of empirical science itself. But associationism is only one view; it is not a necessary view.

In this article, I would like to sketch an alternative position and present some experiments that

convince me that there is exciting and productive work to do when we approach our field from another perspective. I will argue that this position alters the way we interpret phenomena, emphasizes the importance of natural problems and realistic methodology, and changes what counts as an explanation.

The domain I have chosen is memory. Associationism is most dominant and clearly revealed in this area, and, as I have pointed out, a general associationist account of almost anything leans heavily on memory.

In place of the traditional analysis, I suggest a *contextualist* approach. This means not only that the analysis of memory must deal with contextual variables but also, and this is my point today, that *what memory is depends on context*. This view clashes with the associative view, but I hope that I can convince you that the contextual approach is closer to the truth in the simple sense that it is in better correspondence with experimental data than the usual associative theory.

A Contextualist Formulation

The term *contextualism* is not highly familiar to American psychologists, but it is an American philosophical position that has been intimately intertwined with American psychology for three quarters of a century.² Another name for it is *pragmatism*, and it has its roots in William James, C. S. Peirce, and John Dewey. Unfortunately, to most of us the term pragmatism refers to only one aspect of the total philosophy, namely, the use of practical criteria for judging "truth." That aspect is not the one I want to emphasize here, nor is it the aspect that bears most directly on conceptions of memory. Hence, I have chosen the less familiar, but more descriptive, name *contextualism*.

Contextualism holds that experience consists of *events*. Events have a *quality* as a whole. By quality is meant the total meaning of the event. The quality of the event is the resultant of the interaction of the experiencer and the world, that is, the interaction of the organism and the physical relations that provide support for the experience. The relations can be thought of and analyzed into *textures*. A texture in turn consists of *strands* lying in a *context*.

² For an introduction to contextualism and its contrast with mechanism, the reader is referred to Pepper (1970).

Consider as an example of an event a listener hearing a sentence. The total meaning of the sentence in that context is the quality of the event. We might note that the event persists in time over some period but that all of it at once forms a single, unified psychological moment. This is the "specious present" of William James—the span of dimensionalized time is psychologically unified in experiencing the quality of the event. The textures that support the quality of the event are those of the hearer and those of the world. If our concern is with the qualities of the utterance, we can turn our attention to its texture, which consists of the words and grammatical relations between them in that context. Within that texture we can easily make out strands that make up the phrases. We can also see that some of the strands extend across the context of the phrases, that a word in one phrase depends on or determines a word elsewhere. We can become aware of the choices and presuppositions that the analyzed strands refer to. Some words and phrases can be shown to acquire their exact meaning *in that event* from their relations to more far-flung aspects of the context: a gesture, a reference, a topic previously spoken of, an event known to both the speaker and the hearer to be in the future, presumed common knowledge, and so on.

In this fashion, the analysis of the utterance will proceed far beyond the immediate physical context of the sentence and far beyond the physical stimuli immediately present. For the contextualist, no analysis is "the complete analysis." All analyses eventually "sheer away" from the event into more extensive contexts. This argues that there is no one analysis, no final set of units, no one set of relations, no claim to reducibility, in short, no single and unified account of anything. What makes an analysis good or bad for us is its appropriateness for our research and science and its utility in our pursuit of understanding and application.

There is a crucial difference between associationism and contextualism. Associationism asserts that there is one correct and final analysis of any psychological event in terms of a set of basic units and their basic relations. When you have reduced an event to these terms, you are through; the job is done once and for all. The contextualist takes the much less comfortable position that a "complete" or "final" analysis is a myth, that analyses mean something only in terms of their utilities for

some purposes. This means—that being a psychologist is going to be much more difficult than we used to think it to be. And it means that the domain of experimentation and experimental methodology will have to be criticized more intently than we thought necessary before.

Before I can persuade you to join in these discomforts, I am sure that I must offer you something better than exhortations. Let us see if this view contributes to the generation and understanding of experiments.

Experimental Examples

I want to put before you three types of experiments that we have been performing in our laboratories at Minnesota during the last few years. I think each type illustrates some important aspect of the contextualist's position. The free-recall studies, which we will consider first, showed us the importance of "comprehension" in determining the quality of an event. The experiments on the recognition of events, which we will consider next, showed us the *unimportance* of contiguity in time and taught us some novel things about the activity involved in the recognition of related and unrelated items. Finally, the studies of the integration of information, which we will consider last, brought both of these together and showed us that the subject's orientation toward comprehension changed the nature of what was remembered in such a way as to produce radical changes in recall and recognition.

FREE RECALL

The free-recall experiments started innocently enough in pursuit of an answer to a simple question: If we could get subjects to attend to the meaning of words, would they show more associative clustering in recall than subjects who attended to other aspects of the words?

Associative clustering is an old phenomenon (Jenkins & Russell, 1952). If one presents stimuli and responses from a word association test in random order and asks subjects to recall the words, the subjects cluster the associates together in recall. For example, if the list of words contains *table*, *king*, and *salt* early in the list, and words like *chair*, *queen*, and *pepper* later in the list, the subjects will recall the words out of order; that is, they will tend to recall *table* and *chair* together, *king* and *queen*

together, and *salt* and *pepper* together. In the late 1950s we assumed that this effect was an automatic consequence of associative strength, but in the 1960s we thought we had better take another look at it. Tom Hyde and I (Hyde & Jenkins, 1969) decided to see whether *what the subject was doing* when he heard the words had an effect on the recall phenomena.

For a task that would require *comprehension* of the stimulus words, we asked the subjects to rate whether the words were pleasant or unpleasant. For noncomprehension tasks we decided to focus the subjects on the *form* of the words; we asked them to indicate whether the words they heard would be spelled with an "e," or we asked them to estimate the number of letters in each word. We called these *formal* tasks. All subjects heard the same word list in the same order via a tape recorder.

The results were very interesting. When subjects performed the task that required that they *comprehend* the words, their recall was excellent and they showed a high degree of associative clustering. They were as proficient in recall and clustering as a control group of intentional learners who performed no orienting task at all! On the other hand, the subjects who performed the *formal* tasks recalled only half as many words and showed little associative clustering. (As the literature suggests, whether the learning was incidental or intentional had no appreciable effect on recall for any of the groups doing orienting tasks.) It was impressively clear that the most important determiner of recall was the nature of the *event* the subjects experienced when their task brought them into contact with the stimulus words. This finding suggests that subjects recall the quality of the events they have experienced, not stimuli to which they have been exposed. And in spite of the fact that we often think of comprehension as automatic for skilled readers and listeners (such as our subjects), a radical difference appears in recall between subjects who were required to comprehend the words and those who were not.

As contextualists we must say that the occurrence of the word on the audiotape is no guarantee of any particular experience for any auditor. The quality of his experience is determined by the interaction that he has with the physical texture presented. That texture can provide support for many different kinds of experience. In this simple case, the quality of the experience is governed

largely by the task instructions that we have given the subject insofar as they affect his comprehension of the words.

But the associationist is not easily upset by this experiment. He draws our attention to explanations that do not have recourse to terms like *comprehension* and *quality of events*. And he objects that the phenomenon is limited. Let us look at some of these arguments and objections briefly:

"Maybe," say the critics, "the results are due to the number of units each group has to consider. The comprehension groups deal with words; the formal groups deal with letters. The formal groups are penalized because they have to think about a lot of units and the recall is in terms of the kinds of units the comprehension group is using." Fair enough. Let's change tasks and see if this possible explanation holds up.

Carroll Johnston and I (Johnston & Jenkins, 1971) selected *rhyming* as our formal orienting task, and we selected *appropriate modifiers* (giving adjectives for nouns and nouns for adjectives) for our comprehension orienting task. Thus, all subjects listened to words and wrote other words in response. The results duplicated the first experiment. The subjects doing the formal task (making rhymes) showed poor recall and little clustering. The subjects performing the task that required comprehension showed recall and clustering essentially like that of the intentional learning group, which had no orienting task to perform. Exit the first counterhypothesis.

It was suggested that the effect relied entirely on the organization made possible by the associates in the list and that the tasks did not really affect recall of individual words. This notion was quickly refuted by running comparable experiments with both related and unrelated words (Hyde & Jenkins, 1973). Tasks requiring comprehension resulted in twice as much recall as tasks that did not require comprehension, even including tasks like assigning parts of speech to the words.

The third and fourth alternative explanations usually arose together, although they are contradictory. We call them the *time hypothesis* and the *effort hypothesis*. The arguments are as follows:

The time hypothesis. The tasks requiring comprehension must be easy. The subjects do them rapidly and have the remaining time for rehearsal. The formal tasks take more time and, thus, these subjects have little opportunity to rehearse. The

differences you find are due to differential opportunities for rehearsal.

The effort hypothesis. The comprehension tasks are difficult. These subjects must pay more attention and devote more effort to the task in processing words. Thus, they remember more readily. The formal tasks do not require much attention or effort and thus are not remembered.

David Walsh and I (Walsh & Jenkins, 1973) tackled these "mirror twin" hypotheses in an unorthodox kind of study that Walsh invented. His method is as follows: Take a list of words. Determine their recall level with a good comprehension task. Determine the recall level with a formal task. Now, *using the same time intervals for presentation*, ask new subjects to do *two tasks* in the interval for each word. If the time hypothesis is correct, recall on any combination of tasks should be poorer than recall on either task alone. If the effort hypothesis is correct, recall on any combination of tasks should be better than recall on either task alone. However, if the quality of the experience is the important factor (as we supposed), then comprehension tasks should produce good recall whether they are performed alone or in combination with some other task. However, formal tasks should result in poor recall alone and in combination with each other. But when they are combined with a comprehension task, they should not detract from it.

This reasoning presents a nice experiment. If the time hypothesis is correct, all combinations of tasks will yield poor recall. If the effort hypothesis is correct, all combinations will result in improved recall. If the contextualist position is correct, those combinations containing a comprehension task will result in good recall and those combinations that involve only formal tasks will result in poor recall.

In an extensive series of experiments with many different kinds of formal tasks, the outcome was clearly in favor of the qualitative contextualist position. Both the time and the effort hypotheses were defeated. Comprehension tasks, alone or in combination with anything else, resulted in recall as good as that of an intentional learning group that performed no orienting task. Combinations of two formal tasks resulted in poor recall. (See Hyde, 1973, for an independent replication.)

The last candidate for an alternative explanation was related to the feeling that something

about the experiment was artifactual. Perhaps, our colleagues suggested, the general "set" of the subjects was affected in some way by the comprehension instructions—that it was not the particular task or the fact that it required comprehension but, rather, that the subjects developed a different set which somehow affected the recall. Now, surely, overall set has an important influence on the outcome of an experiment, but our particular analysis denied that the effects we were getting depended on such an overall orientation.

To investigate this problem, Robert Till and I (Till & Jenkins, 1973), following a suggestion from Endel Tulving, performed a series of experiments with a within-subject, within-list design. In this experiment each subject performed each kind of task. The subject heard each word followed by a letter, for example, *table—A*. The word was the object of his attention as usual. The letter was a cue that told him which task to perform on that particular word. Some tasks required comprehension of the word and some did not. The technique permits the comparison of the recall of words that have been involved in comprehension tasks *versus* formal tasks for each subject during a single list presentation.

The results are reassuring with respect to the earlier analysis. Subjects recalled twice as many words from the subsets on which they performed comprehension tasks as they did from the subsets on which they performed formal tasks.

These experiments, and many others that we have performed, convince me that the best way to think of this experiment is in the contextualist's framework, taking the *event* to be the interaction of the subject with the individual word. The quality of this event is radically different in tasks requiring comprehension from the quality of the event when comprehension is not required. These differences in quality are reflected in the radical differences observed in recall.

How could you further enhance recall of the word list? For the contextualist, a reasonable move would be to develop a situation in which context was even more novel and the comprehension had to be developed in some special manner related to that context. Buford Wilson and John Bransford (personal communication, August 15, 1973), reasoning in just this fashion, created such an experiment. They asked one group of subjects to rate each word as "pleasant or unpleasant to you if you were on a desert island." As they pre-

dicted, the recall of words by this group was even better than the recall by the usual "pleasant-unpleasant" rating group.

I must also point out before going on that the analysis given here applies equally well to other tasks that we know will facilitate the free recall of single words: tasks such as asking subjects to form images, to rate words for vividness of imagery, to sort words into semantic categories. If the task requires comprehension, the quality of the event is such that it is readily recalled.

EVENT RECOGNITION

Let us proceed to another type of experiment that I will call *event recognition* for want of a better name. What I want to illustrate here is that the phenomena we find in recognition depend on the quality of event that the subject constructs from the experimental material during the acquisition phase of the experiment. (In the free-recall studies we kept the materials constant and showed the effects of varied tasks; here we will keep the tasks constant and show the effect of varying the materials.)

For our experimental example let us take the exciting and original work of John Bransford and Jeffery Franks on the abstraction of linguistic ideas (Bransford & Franks, 1971). For our purposes, the seminal study they invented as graduate students can serve as the key illustration. The material in the study was a set of sentences. The subjects were asked to listen to the sentences, hold them in memory for a few seconds, and answer an elliptical question about each one. Although there were no instructions about the nature of the sentences that were used in the experiment, it is apparent to even a casual listener (or reader) that the sentences fall into four interrelated groups. Each group of sentences consists of the "elements" of some overall event, taken one, two, or three at a time in various sentence compositions.

A typical set of sentences that a subject might hear in such a study is given in Table 1. The reader who has never participated in such an experiment is invited to read each acquisition sentence, one at a time, count to five, answer the question, then go on to the next sentence, repeat the routine, etc. The reader should then take the recognition test. The best way to understand the experiment is to experience it.

After the acquisition set was read to the subjects, the recognition set of sentences was pre-

sented and the subjects were asked to judge whether they had heard each sentence before and to give a confidence rating to the judgment.

The results of the study are just the opposite of what one would expect from an "associative-link" model of memory. In general, the subjects are *certain* (with ratings between +4 and +5 on a scale of 5) that they have heard the full, complex sentences that describe the four events. In fact, of course, they have not heard those sentences, nor have they even heard any sentences that long. As the sentences get shorter and shorter (down to "The cat jumped on the table" and "The girl lives next door"), the subjects are less certain about whether they heard them or not, although they generally believe that they have.

Whether the sentence actually occurred or not in the acquisition set has very little influence on its rating as long as it is one of the possible sentences that describe the event. (In the recognition set given in Table 1, for example, no "old" sentence is presented, yet subjects will estimate that from 5% to 80% of the sentences were presented earlier.) If, however, the sentences are mixed (e.g., "The scared cat running from the barking dog broke the window"), or if a new arbitrary fact is introduced ("The tall girl who lives next door broke the window"), subjects reject the sentence with certainty.

What has happened here is clear to the contextualist. The subjects have used the various strands repeatedly available in the texture of the experiment to construct four events that are completely described by the four long, complex sentences. The quality of each of the events is indeed the total meaning of the complex sentence. Once the fusion of the strands into events has occurred (particularly since the strands are heard over and over again in various combinations), the subject cannot perform an analysis to recover the exact pattern of input that furnished support for the construction that he made.

The analysis here is very much like the contextualist's account of the development of science—pulling together separate strands and seeing the unity of events even though they are not presented contiguously in time or space. The notion of *fusion* is an old one in the contextualist tradition and is often appealed to in explanation of the paucity of analysis available in aesthetic experience or mystical experience. (And I might suggest in passing that in the case in which highly fused

Sample Experiment

STOP. Count the number of sentences judged "old." See text for answer.

events arise from strands that are not systematically presented, historical reconstruction as to the sources of the event will, as a general rule, be unsuccessful.)

Regardless of our particular analysis, it is clear that the phenomena disclosed by these experiments pose formidable problems for storage theories of memory. Selection and integration of relevant strands and the accompanying phenomena of fusion are stubborn facts that cannot be set lightly aside. But such facts are not easily discussed in the associative framework.

If one wants to "push" the contextual analysis a little, an enlightening experiment is one that keeps the superficial form of the basic experiment above, but changes the quality of the *events* involved. If one takes away the "contextual glue" of the four themes, the results of the experiment change in dramatic ways. Peterson and McIntyre (1973) presented individual, *unrelated* sentences of the same length and grammatical structure as in the original experiment. When they examined recognition data for sentences that were actually presented, they found that the recognition confidence curve ran in the opposite direction. With *related* sentences the subjects were sure that they heard the long, complex sentences, but were uncertain about the short, simple ones. With *unrelated* sentences, subjects were sure about the short, simple sentences, but were uncertain about the long ones. Of course, in a study with unrelated sentences, the only *events* available to the subject are the individual sentences themselves. The shorter and simpler the event, the more likely the subject can satisfy himself that it is really the same; the longer it is, the less likely he is to have integrated the event and the more possibilities there are that something is different. Thus, the sentence-length-recognition function can be reversed by changing the quality of the event. As the quality of the event changes, the results change predictably.

We must also notice that the phenomena that are apparent here are equally evident in a host of psycholinguistic experiments. The studies by Sachs (1967) on memory for form and content of sentences in stories illustrate both the salience of quality and the effects of fusion. When her subjects were queried about a sentence that was embedded in the context of a story, the *form* of the sentence was incompletely remembered. The *meaning* of the sentence, however, was readily retained

because it was an integrated strand in the texture of the larger event. Violations of meaning or sense were readily detected, but form vanished with the specious present.

If we contrast Sachs's study with the psycholinguistic experiments that have used *unrelated* sentences (e.g., Clifton & Odom, 1966), we have another illustration of recognition phenomena changing when the quality of the event changes. In the psycholinguistic experiments, for example, the syntactic form of the sentence is systematically related to false recognition and false recall, but the truth or falsity of the content described by the sentence (the difference between affirmation and negation) is no more important than whether the sentence is active or passive in form. The point is, of course, that there is no context in which the content of the sentence makes any sense or any difference. Hence, affirmation and negation have only syntactic meaning. That is, if each sentence is an unrelated event, then only variables at the level of construction of the sentence are of any importance.

Experiments on miniature linguistic systems reveal similar phenomena. If subjects are trained to label items in a color-form matrix such as that used by Esper (1925), they learn the *system* but ordinarily do not remember which specific instances they were given in the training trials, even though they may have seen the same instances many times. In general, memory is for systems, not for instances. With a small set of examples, subjects may remember particulars. With a liberal set of examples, however, they cannot reliably discriminate the instances on which they were trained from other acceptable instances in the system (Foss, 1968; Keeney, 1969; Segal, 1962).

INTEGRATING INFORMATION

I want to present a more complex task that requires a good deal of work on the part of the subject. In this experiment the subject must "problem solve" to achieve the complete event that we want him to apprehend. This experiment was developed by J. Richard Barclay (1971) in extending the work of Bransford and Franks. Barclay's experiments show both of the phenomena that we have noted earlier. First, changing the subject's task changes the kind of event that the subject experiences. Second, taking sentences as events results in very different recall and recognition be-

haviors than those observed when the entire experience is integrated into a single event.

In several different experiments, Barclay presented subjects with sets of sentences. The sentences gave a piecemeal account of the pairwise relations of a series of five objects that were arrayed on some dimension such as left-right or taller-shorter or faster-slower; for example, there might be five animals standing in a left-right array, five men varying in height, or five cars varying in speed.

The "comprehending" subjects were told that they would hear sentences describing the relations between the five animals (or men, or cars) and that they were to listen carefully to the sentences so that at the end they could properly line up the objects in order. The control subjects were told that they would hear a set of sentences that were about animals (or men, or cars) and that they were to try to remember the sentences that they heard. After hearing the sentences several times, the subjects were given a comprehension test and a test of sentence recognition or recall.

The first result of the experiments was the obvious finding that 80%-100% of the comprehending subjects constructed the correct array of objects, but only 0%-10% of the subjects who were trying to remember the sentences could do so. The second result was that the comprehending subjects were excellent in discriminating true sentences from false sentences but could not remember which of the true sentences they had actually heard. All of the true sentences seemed familiar to them, and about equally so, whether they were original sentences, correct paraphrases, or correct inferences from the original sentences.

The group that was specifically told to remember the sentences presented quite a different picture. These subjects were poor at recognizing which of the sentences they had heard and almost equally poor at separating true sentences from false ones. In other words, when subjects considered the sentences as the events of the experiment, they learned very little, their confusions were determined by variables at the sentence construction level, and they showed evidence of massive interference. With the array itself as the event to be constructed, specific sentence memory was essentially nil, but the general constraint of what was an acceptable or "true" sentence was virtually perfect. The same results were obtained in recall experiments. The comprehending subjects recalled *no* false sen-

tences and "recalled" true sentences independently of whether they had heard them or not.

This experiment is a dramatic example of the principles we have encountered in both of the foregoing types of experiments. First, what the subject was instructed to do with the input was the most important determiner of the nature of what was remembered. Second, when the event itself was well fused, the specific instances from which the event was constructed were not readily discriminated. Finally, the availability of the global event in this case makes it possible for the subject to reject one class of sentences (the false ones) and to accept another class of sentences (the true ones) as likely to have occurred even though he could not discriminate what actually occurred. That is, the event (the representation of the array which is remembered) is related to sentences in such a way that permissible utterances can be generated or recognized with great accuracy even though actual, historical sentences cannot. *What* is remembered is definitely not verbal and probably not even linguistic, but, it plays a key role in determining which linguistic constructions are recognized and recalled.

Discussion

What kinds of lessons can we draw from these experiments? First and foremost, I think it is clear that we should shun any notion that memory consists of a specific system that operates with one set of rules on one kind of unit. What is remembered in a given situation depends on the physical and psychological context in which the event was experienced, the knowledge and skills that the subject brings to the context, the situation in which we ask for evidence for remembering, and the relation of what the subject remembers to what the experimenter demands.

Contextualism calls us back to considering what the subject believes and knows when we talk of memory. It simultaneously suggests that we look to the sources of this belief and to the subject's ways of constructing and reconstructing his experience. William James pointed out that the only thing that distinguishes memory from the other higher mental processes is just that belief. He argued that there is nothing unique in the object of memory and no special faculty evident in its manifestations. Apart from the belief that the con-

struction of the mind is attributed to the past, he saw nothing to set memory apart from perception, imagination, comparison, and reasoning.

Such a claim is unsettling because it says: *Memory is not a box in a flow diagram*. It is also threatening because it seems to demand an understanding of all "the higher mental processes" at once. Yet, that is what the data of our experiments suggest. Surely these studies imply that we cannot deal with memory without dealing with instructions, perception, comprehension, inference, problem solving, and all the other processes that contribute to the construction of events. The theoretical contextualist agrees. He argues that there is no other approach. To study memory without studying perception is to invite disaster in one of two ways: on the one hand, failing to understand the inputs to the subject or, on the other hand, pushing all the difficult problems out of memory into the unknown perceptual domain for someone else to study. To study memory without studying inference is to be baffled by the transformations that the subject puts on his experience. To study memory without studying language is to be confounded by paraphrase and the issues of meaning. And so on.

The contextualist avoids despair at this point, not by predicting success for a global assault on all higher mental processes simultaneously but by asking again, "What kind of an analysis of memory will be useful to you in the kinds of problems you are facing? What kinds of events concern you?" If you limit the events for some purpose, he will lead you into an analysis of context, textures that support experiences, strands that interrelate aspects of experiences, etc.

You should notice that methodological issues and the choices of experimental paradigms become crucial when you take the contextualist view. It is *not* true in this view that one can study any part of the "cosmic machine" to just as good an effect as any other part. The important thing is to pick the right kinds of events for your purposes. And it *is* true in this view that a whole theory of an experiment can be elaborated without contributing in an important way to the science because the situation is artificial and nonrepresentative in just the senses that determine its peculiar phenomena. In short, contextualism stresses relating one's laboratory problems to the ecologically valid problems of everyday life.

Conclusion

It would be easy to believe from this brief presentation that contextualism is merely eclecticism given a fancy name. It would also be easy to suppose that my plea is for miniature theories that will eventually integrate into a global theory. And it is easy to imagine that all of us could be contextualists and at the same time continue working in just the same fashion that we always have on associative theories. But none of these beliefs is correct.

Contextualism is historically tolerant of other approaches and is always willing to examine a claim that the cosmic machine is all of one piece. But at rock bottom there is a profound difference in belief between *associationism*, which presupposes fundamental units and relations out of which all else is constructed, and *contextualism*, which presupposes that events are primary and that the quality of events determines what the possibilities are for a host of analyses.

The associationist finds that semantic features (or word associates or images or what-have-you) are important in predicting recall of individual words. "Fine," says the contextualist, "but do not bet any appreciable amounts of money that those will be important considerations when you combine words in sentences or embed them in different contexts."

The associationist finds that grammatical features are predictive of memory distortions in single sentences and believes that he has a theory of comprehension. "Look out," says the contextualist, "those are unlikely candidates for relevant variables for understanding sentences in context." And so it goes.

The contextualist does not believe in one order of phenomena that dominates the psychological world. He does not believe that there is a single paradigm of explanation such as mechanism. Explanation for the contextualist consists of explicating *for some purpose* the quality of an event that we find important or interesting. That entails in turn a description of its spread in time and its degree of fusion. It further calls for a discussion of the textures that support the quality of the event and the strands making up the texture and relating it to relevant aspects of its context. Unlike the associationist explanation, the contextualist explanation is put together from the top down, rather than from the bottom up; and it is oriented toward

the event rather than toward the supposed machinery.

I believe that the field of memory research is moving toward contextualism, and I, for one, welcome it. I think that an awareness and acceptance of this movement will free us to explore the ecologically valid problems of memory that are of real importance to us. I think it will help us to be alert to the identification of new, emergent phenomena as they are encountered. In short, I think that contextualism provides a real, viable, and optimistic alternative to the oldest theory of them all.

Translations in Gerontology— From Lab to Life *Utilizing Information*

DAVID SCHONFIELD *University of Calgary, Alberta, Canada*¹

When elderly people are asked to participate in investigations on aging, they sometimes object strongly and question the fundamental assumption underlying such research. They suggest that one older person differs so much from another that the quest for generalization is pointless. Although it is easy to attribute such reactions to a negative attitude toward the idea that behavior is in any respect predetermined, the laboratory itself justifies certain reservations. The journey from lab to life must begin with the finding that there are usually greater differences among a group of older people than among the young. In other words, standard deviations tend to increase with age. Figure 1, taken from Heron and Chown (1967), is a typical illustration. Each dot represents one score from a male sample on the Progressive Matrices Intelligence Test, a test of the ability to utilize information. Some people in their 40s, 50s, and 60s do better than the average 20-year-old.

Editor's note. The public demand that psychological research become "relevant" can be met by a demonstration that laboratory findings are indeed relevant to life's problems. In order to apply such findings, a crucial step of translation is required to bridge the gap between the conclusions of experimental investigators and solutions to practical difficulties. The need for bridges is nowhere greater than in gerontology because problems of the aged are so severe. Therefore, the Division of Adult Development and Aging (Division 20) of the American Psychological Association requested three renowned contributors to the literature on performance and aging to make the difficult translation from research findings in the laboratory to the multitude of problems of the aged. This article by David Schonfield and the following two articles by K. Warner Schaie and James E. Birren, respectively, are their responses.

¹ This work was supported by the Canadian National Research Council (APA 89).

Requests for reprints should be sent to David Schonfield, University of Calgary, 2920 24th Avenue, N.W., Calgary, Alberta, Canada T2N 1N4.

More importantly, there are a few scores among these older groups as good as the best of the younger crowd. It is the lab that provides the caveat for planning and action solely based on average scores. Older people are slower on the average than the young, but it would be wrong to exclude all older workers from jobs that require fast responses—some of the old are just as fast as the young. Sexual drives tend to decrease with age, but a prospective marriage partner with 20 year's seniority may well be one of the many exceptions to that rule. There are, of course, exceptions to rules about the young, too, as can be seen in the 30s and 40s (see Figure 1). However, in general, we can say that there are more older people who behave like the young than young people who behave like the old.

A second pitfall to avoid in the journey from lab to life is due to relativistic and impermanent connotations of the terms *old* and *young*. In Canada a few years ago we considered that we had elected a young prime minister, aged 48, but as a bridegroom of 50, we thought of him as old. In experimental studies, we similarly find that those between 35 and 45 are occasionally labeled as young compared to a group with an average age of 70, but labeled as old compared to a 20-year-old group. The results of such studies are summarized in sentences that begin, "With age, such and such occurs." From the applied point of view, it is of fundamental importance to know whether the difference is between the ages of 20 and 40 or between 40 and 60. The extrapolation type of error is less frequent than the interpolation error, because most studies of human performance employ a group of subjects in their early 20s and another group over 65 years of age, with no one in between. Again the findings are summarized as, "With age, there is deterioration in something or other." The

Figure 1. Progressive matrices (men): Distribution of 40-minute scores with means indicated by horizontal lines. (From *Age and Function* by A. Heron and S. Chown; London: J. & A. Churchill, 1967. Copyright 1967 by J. & A. Churchill. Reprinted by permission.)

suggestion of a gradual and equal decline in each decade between 20 and 70 is unlikely to be correct. When there are only two widely separated, empirically established points on the graph, it is wrong to join them by a straight line and suggest that this represents the age dimension. Figure 2

(Bromley, 1966) provides examples of this kind of interpolation. All of the decline may occur during one or two decades, with a plateau or even improvement during the remaining periods. Personnel officers and policy makers can justify on this basis their refusal to employ people over 45

Figure 2. Relative age differences for several biological variables expressed as a percentage loss of function from 100% at the age of 20. (From *The Psychology of Human Ageing* by D. B. Bromley; Baltimore, Md.: Penguin Books, 1966. Copyright 1966 by Penguin Books. Reprinted by permission.)

or to press for the early retirement of those in their 50s. In general, we are abysmally ignorant concerning stability and change of behavior during the middle adult years. Be that as it may, the journey from lab to life must begin and end with the same flight number; we should not leave the lab with the 70s and arrive in life with the 40s.

A third methodological issue concerns the absence of age differences in the ability to utilize information. From the applied point of view, any human capacity that shows no difference or minimal change during the adult years should be pinpointed and highlighted. It is on the basis of such conservation of ability that older people can compensate for losses in ability. The theoretically oriented scientist often ignores findings that show no change with age. He is searching for signs of aging, and the absence of an age change is there-

fore only of tangential interest. Psychologists should not follow, what might be called, the *biological model* in this regard. We need to emphasize the absence of age differences in order to counteract negative attitudes toward aging. It is just not true that every day in every way we get worse and worse. Situations in which older people have special problems in acquiring information, recalling information, or utilizing information are also of fundamental interest. If such situations can be circumvented, competence can be increased and strain avoided. The most valuable findings of all are those in which the manipulation of one or more variables results in large reductions in age differences. Useful translation from gerontological research to life becomes reasonably straightforward when we can specify situations in which age differences are diminished or disappear.

Information Presented in Unusual Ways

Applied implications of many simple, theoretically based laboratory findings are often easy to envisage. It is not even essential to undertake the physical journey from lab to life—a little imagination suffices for the busy commuters between lab and conferences. Take as an example one of the earliest controlled studies on age effects. Ruch (1934) found that the difference between a middle-aged and an elderly group was much greater when spatial information was provided through a mirror as compared to direct vision. The looking glass difficulty for those over the age of about 55 has been confirmed in settings other than the pursuit rotor task which Ruch employed (Welford, 1958). This difficulty coincides with a general principle about the problem of overcoming longstanding habits. Therefore, we are warranted in alerting those who use mirrors in the "real world." Physiotherapists and speech therapists, for instance, often attempt to provide feedback by means of a mirror when rehabilitating patients following a stroke. During the initial learning period this kind of crutch is likely to be less helpful to the aged than to the young. Ruch's major concern was with the plasticity of nervous tissue, but that theoretical issue becomes superfluous baggage in our journey from the lab. There is at least one danger in this kind of translation of gerontological research. The message that the elderly have difficulty with mirrors and that extra encouragement coupled with patience is required for them can be-

come distorted into a recommendation that mirrors should be avoided in rehabilitation work with older patients. This possible harmful outcome is due to the prevalent carelessness in the use of language which has coincided with our obsessional carefulness about experimental design. An exception to the generalization about the age-associated looking glass difficulties is derived from another conclusion of gerontological research. Well-established skills that continue to be practiced show minor deficits compared to age difficulties in acquiring a new skill (Szafran, 1968). There does not seem to have been any specific investigation on this point with respect to mirrors. Nevertheless, applied psychologists should not be afraid to make the pronouncement that older dentists, for instance, will not experience special difficulties when using mirrors to examine teeth, providing they had their training when they were in their 20s or 30s. On the other hand, starting a second career as a dentist at the age of about 55 is likely to cause problems in utilizing and combining information derived from mirror vision and direct vision.

Ability to Ignore Irrelevant Information

We turn now from information presented in an unusual way to an age decrement in the ability to ignore irrelevant information. Only one report seems to have been published focusing specifically on the topic, and in that experiment of Rabbitt (1965) the older group's age was over 65. However, an increase in distractibility beginning probably at about 45 is suggested by a number of studies. The evidence on difficulty in identifying concealed figures (Basowitz & Korchin, 1957), in maintaining sets (Talland, 1959), and in maintaining performance on dichotic listening (Schonfield, Trueman, & Kline, 1972) all point toward a problem of excluding from attention material irrelevant to the task at hand. Distraction by irrelevant stimuli is an all-pervasive hazard in the real world, and innumerable examples could be cited in which special consideration should be given to this age-related difficulty. If one does not stick to the main point in conversations with older people information is less likely to be utilized and misunderstandings will ensue. On the other hand, the reputation that the aged themselves have for not sticking to a point can be considered a manifestation of distraction by their own irrelevant memories. When an older person is engaged in the

more dangerous pastime of driving an automobile, distraction by the irrelevant reduces utilization of the vital relevant information. The translation from lab to life should result in the banishing of unnecessary billboards and road signs, especially on busy thoroughfares. Similarly, there should be a general discouragement of conversation when an elderly person is driving during rush hours or driving a new car or driving in a strange city. In other words, if an activity requires greater concentration and if the absence of concentration can result in injury or accident, special procedures are needed to avoid distraction on behalf of the elderly population.

Speed and Timing

The third example of simple translation from lab to life is derived from the area of speed and timing covered in Birren's article (see pp. 808-815, this issue). Field research in the early Cambridge studies showed that workers in their 50s tended to leave jobs in which performance was paced by a machine or another external source (Welford, 1958). Older workers seemed to have little difficulty, however, in continuing to hold up well in self-paced tasks. The reverse journey from life to lab produced experiments suggesting that acquisition of information was not readily time shared with decisions about responses to be made. Later studies, in particular those of Eisdorfer (1968), led to the conclusion that time limitations can be emotionally upsetting for older people. Ordinary conversation, especially with busy people, often resembles an externally paced task. The questioner impatiently waits for a response while the respondent is attempting both to understand the question and to prepare an adequate answer. By the time an elderly person is ready to talk, the questioner has given up and a new question is posed. Those who are in constant contact with the elderly—family, civil servants, and social workers—should convey an unhurried impression in order to avoid an inquisitorial atmosphere with all of its emotional outcome.

Threshold Level

The raising of thresholds is the source of the fourth translation example. Food remaining near the mouth after eating and the occasional drip of mucus on the nose are sometimes not felt by a

younger person. The sensation is at about threshold value for the young and more likely to be below the touch threshold in older people. Alerting the elderly themselves to this kind of reduction of information input could have valuable benefits. Social relationships seem to become more precarious as we age, and they are likely to suffer when appearance is somewhat repulsive. Here, the recommendation is an extra check in the looking glass as opposed to the earlier example of a reduced usefulness of mirror vision.

Learning and Memory

The next translation example comes from learning and remembering. Theorists wish to pinpoint the locus of the age-associated deficit: Is it short-term memory? Is it acquisition? Is it the transfer from short-term to long-term memory? Is it retrieval? The practical implications, however, of increasing difficulties in reproducing newly acquired information are often straightforward. Surely we can tell physicians that they should provide written instructions for their elderly patients, so that memory can be checked. After verbal instructions, the patient is less likely to remember whether the doctor said, "Do it three times a day," or "four times a day." Did the doctor say, "Swallow the medicine," or "Place it in the anus"?

Caution

The last example in this series emanates from the tendency toward increased caution with age. Botwinick (1966) has been the major contributor to the literature on this point, but others such as Szafran (1951) in his studies on utilization of vision and Canestrari (1963) on omission errors provide confirming evidence. As we get older we adhere not only to the advice to look before we leap, but we also seem to prefer to look while we are leaping. Industrial gerontologists can use these findings in the counseling they provide about suitable jobs for middle-aged and older workers. Inspection types of occupations, in which carefulness is at a premium, are probably ideal occupations for these age groups.

Conclusion

These six illustrations—use of mirrors by dentists and others, irrelevant information and driving, self-

pacing in conversation, threshold touch sensation and its social implications, aids to remembering physicians' instructions, inspection-type jobs—suffice to exemplify one approach to translations in gerontology. A specific finding in the lab is recognized as an example of a more general principle, and a jump is made from the finding to a closely analogous situation in the "real world." A prerequisite is considerable knowledge of the discipline so that the practitioner recognizes which specific findings are supported by other investigators. The jump is a nonscientific activity and could perhaps be labeled gerontological common sense. It has been suggested elsewhere (Schonfield, 1972) that all research workers should be encouraged to make this jump by including a section headed "Proposals for the Application of Results" at the end of published articles. The principles will vary according to the breadth of their potential applications. When the breadth is narrow, as in the case of the looking glass example, they might be called "princippettes," and progressively wider applicability would become queen-size principles—for example, the irrelevant information finding—and king-size principles. (The nomenclature is derived from bed size and perhaps because of that it smacks of male chauvinism.)

A king-size principle suggested by the six illustrations is that functioning requires increased attention from about the age of 50. Attention to more than one activity cannot be shared, and concurrent multiple functioning becomes increasingly difficult. Processing of input requires attention because the meaning of signals does not occur so automatically. Processing of output requires attention because "actions do not take care of themselves." (That phrase was used by Sir Frederic Bartlett some 25 years ago in an unpublished lecture.) The fact of time pressure is attended to instead of being ignored, perhaps because paying attention has become a habitual strategy both for relevant and extraneous facets of the task. Even psychological functions, such as remembering, do not "take care of themselves" and remembering to remember demands vigilance. The principle of extra attention has implications for almost all situations in the everyday life of older people.

The use of the term *principle*, rather than *theory*, in these descriptions of translation from lab to life has been deliberate. Following Broadbent (1971), I confess to "distaste for the amount of theory current in psychology" with its "stream of papers giving hypothesis, prediction and verification [p.

5]." Although there is no inherent contrast between theory and practice, the attitude prevails that a theory has greater theoretical value when it has minimal applied value. The pursuit of principles rather than theories and hypotheses may help gerontologists to keep applications at the forefront of our attention. Broadbent (1971) rightly said:

The researcher remote from practical pressures may indeed be free to study major variables in which at this instant society does not seem to be interested, but he should not use this freedom in order to study minor variables, until there are no major ones within reach of our techniques [p. 4].

Translations in Gerontology— From Lab to Life

Intellectual Functioning

K. WARNER SCHAIK *University of Southern California*¹

Developmental psychologists often find themselves in a cross fire between their more traditionally oriented colleagues who distrust the need for the quasi-experiment, which must be one of the major thrusts for the developmentalist, and the clinician or other applied professionals who feel that the data provided by the scientist prove the obvious or are quite unintelligible. It is the purpose of this article to speak to this issue and to show that people like myself do perhaps have ways of combining the rigor of the scientific method with an address to problems that may indeed be of social consequence.

A substantial portion of this article will be concerned with the myth of intellectual decline. That is, I will try to spell out as simply as possible why the presumed universal decline in adult intelligence is at best a methodological artifact and at worst a popular misunderstanding of the relation between individual development and sociocultural change. Second, I will briefly examine some possible ways in which old adults may differ qualitatively in their approach to intellectual performance, paying attention mainly to motivational factors which may indeed interfere in the performance of old adults on intelligence tests as well as life tasks designed for young people. Third, I shall then examine certain social policy implications which follow from the very different reading of the data on intellectual functioning in adulthood and old age which I and my associates have found necessary (cf. also Baltes & Schaie, 1974; Schaie, 1973b).

The Myth of Intellectual Decline

It has long been the popular notion that old people may have much wisdom based on a long life, but that they should not really be allowed to apply that wisdom to any matter of consequence or be entrusted to perform important societal functions because it is assumed that they are no longer capable of sustained high-level intellectual performance. This view has been strongly supported by some of the early cross-sectional studies of intelligence (e.g., Jones & Conrad, 1933; Wechsler, 1939). These studies indeed showed that on comparable tasks, peaks of intellectual performance occurred in late adolescence, with consistent decrement thereafter.

This view was first challenged by some early longitudinal studies of adult intellectual performance (Bayley & Oden, 1955; Owens, 1953) that found maintenance of most intellectual functions at least into the early 50s. Some of this evidence was soon dismissed as being due to the use of highly selected samples or the hypothesis that age may be kinder to the more gifted who were examined in these studies. Nevertheless, it has now become incumbent to take a close look at the issue of the discrepancies between the results of cross-sectional and longitudinal findings, and much of my own work during the past decade has addressed itself to that particular issue (cf. Schaie, 1965, 1970, 1973c).

In order to understand the evidence on intellectual change in adulthood and to infer social implications we must address three issues: The first deals with the question of whether intellectual decrement is a general or specific phenomenon, the second is concerned with the differentiation of ontogenetic changes in function from differences in performance level between generations, and the

¹ See editor's note, p. 796 of this issue. Preparation of this article was supported in part by Research Grant 8458-01 from the National Institute of Child Health and Human Development.

Requests for reprints should be sent to K. Warner Schaie, Gerontology Center, University of Southern California, University Park, Los Angeles, California 90007.

third is concerned with the issue of individual differences in intellectual development.

INTELLECTUAL DEVELOPMENT: GENERAL OR SPECIFIC

The early history of intelligence testing was greatly concerned with attempts to develop homogeneous indices that would maximally predict school performance, and later attempts to develop instruments more suitable for adults maintained the notion of the desirability of a single composite index of intellectual ability. But quite early factor analytic studies showed that there were indeed many different building blocks of intelligence (Guilford, 1967; Thurstone, 1941), and it did not seem unreasonable to assume that such differential abilities might follow different life courses. Such evidence was presented in cross-sectional as well as longitudinal studies (Owens, 1953; Schaie, Rosenthal, & Perlman, 1953). Schaie et al. found that older people did much more poorly on abilities such as spatial visualization and reasoning than was the case for tests of verbal meaning and word fluency.

Cattell (1963) pushed the argument a step further by proposing that there were certain crystallized abilities that were culturally overdetermined, and consequently once an asymptote was attained these abilities should not be subject to decrement, while fluid abilities being basically innate and biologically determined as a species characteristic should consequently also be subject to the decrement phenomena associated with the life rhythm of the species. Although the isomorphism with respect to the physiological base of the fluid abilities as opposed to the acculturated base of the crystallized abilities is currently under challenge (Arnold, 1973), there is evidence that would at least be compatible with Cattell's point of view requiring different developmental histories for different abilities (see Schaie, 1970). This evidence then suggests strongly that old people as a population subgroup perform better on certain abilities than on others. And this seems to be true for individuals as well, so that a single measure of intellectual ability may be particularly misleading for older individuals in describing their actual level of performance.

But the evidence from the cross-sectional studies showing that peaks of performance may occur at different ages for different abilities and that old

people do better on some tasks than on others does not directly address itself to the question whether or not there is indeed decrement in intellectual functioning. This question must now be considered.

COHORT DIFFERENCES VERSUS ONTOGENETIC DIFFERENCES IN INTELLECTUAL FUNCTIONING

More than 30 years ago Kuhlen (1940) alerted us to the problem that not only do people age but so do cultures, and that it is therefore possible that the perceived deficit of the old may be no more than obsolescence in the face of a rapidly changing sociocultural environment. Unfortunately, neither cross-sectional nor longitudinal studies can deal with this question directly. Cross-sectional studies compare members of different age groups at one point in time who are consequently also members of different birth cohorts who must have had differential experiences that may or may not have anything to do with age. It could therefore be argued that the differences found by such studies during periods of rapid technological change ought not be interpreted as age differences at all but rather as evidence for differences in performance level occurring as a function of membership in different generations. But longitudinal evidence does not by itself bring us any further. As I have previously documented (Schaie, 1972), in the behavioral sciences we are forced to accept the fact that environmental impact has profound importance on determining changes in behavior. Consequently any change in performance over time must confound whatever maturational changes are occurring with those events attributable to the unique environmental impact occurring over a given period of historical time which may equally affect individuals at all ages. Results of a single-cohort longitudinal study may therefore be parsimoniously interpreted as being relevant to the chronicling of change occurring at a particular period in time, but not necessarily as reflecting ontogenetic change.

The way out of this dilemma is, of course, the adoption of sequential methods of data collection and analysis (Schaie, 1965, 1973c). Two approaches are needed: The first requires the replication of cross-sectional studies over several points in time. The second involves the carrying of several cohorts over the age ranges of interest. In our own work we have now done both and the

results are indeed revealing. They show with great clarity that a much larger proportion of the variance associated with age can be attributed to generation differences than to ontogenetic change and that both peak levels and slopes of change in ability are changing in a positive direction. In other words, there is strong evidence that much of the difference in performance on intellectual abilities between young and old is *not* due to decline in ability on the part of the old, but due to higher performance levels in successive generations. Some decrement, particularly on tasks involving motor speed, remains to be accounted for, but its onset does not seem to occur until the 60s, and large individual differences remain (Baltes & Labouvie, 1973; Schaie & Strother, 1968b; Schaie, Labouvie, & Buech, 1973; Schaie & Labouvie-Vief, 1974).

We have concluded then that the overall group data require us to consider most of the intellectual decline in the healthy old to be a myth. Nevertheless, we must consider that for given individuals there may indeed be significant decrement with age, but alternatively that there might be growth until very old age.

Two lines of argument should be pursued here. The first is concerned with the evidence that there may indeed be significant decrement in intellectual function for every or most individuals as a precursor to their physical demise. That is, changes in psychological function may occur concomitantly or even ahead of the final period of life. Evidence along this line has been presented by Riegel and others (Reimanis & Green, 1971; Riegel & Riegel, 1972; Riegel, Riegel, & Meyer, 1967).

The second approach to the matter of individual differences comes from a careful analysis of individual life patterns. Such analyses show that at each age-cohort level there are some individuals who (at least over a 14-year period of time) gain and others who lose, while many remain stable (Schaie, 1973a). Moreover, analyses of current life-styles and retrospective history of the very old, as well as the analyses of homogeneous groups of the highly successful elderly, reveal vast differences in the degree to which differences in performance are maintained in the later years of life (cf. Reichard, Livson, & Peterson, 1962; Schaie & Strother, 1968a). In sum, the old are no more homogeneous a group than the young, and aging is no kinder to the able than to those at a low level of functioning (Baltes, Nesselroade, Schaie, & Labouvie, 1972). We may suspect that knowing

more about the microenvironment in which individuals live will give us a better handle on these differences, but work in this area has only begun.

Motivational Factors in the Intellectual Functioning of Old Adults

No matter what interpretation is placed on the comparison of old and young on tests of intelligence it is readily accepted that most of the devices used were constructed for the assessment of young people and that the experience of the old in dealing with the task situation may be quite different, while no doubt the motivational factors operating have altered. These issues will now be attended to.

CAUTIOUSNESS AND RISK-TAKING BEHAVIOR

It has been observed that old people are consistently more cautious than the young. This has been effectively demonstrated by Wallach and Kogan (1961), who used 12 different life situations, and replicated by Botwinick (1966a), who adapted the task especially appropriate for aged subjects. Interestingly enough, older people tended to avoid taking any course of action if this was a permissible alternative. But when risk taking was required it was noted that old people were not more cautious than the young (Botwinick, 1966b). How does this cautiousness apply to behavior on tasks of intellectual ability? Birkhill and Schaie (in press) administered the Primary Mental Abilities Test to a group of elderly subjects under high- and low-risk conditions, each condition further under a choice or no-choice set of instructions. A highly significant Choice \times Risk interaction was found. That is, there was no difference in performance under the no-choice instruction, but under the choice instruction subjects performed significantly better under low-risk conditions. We may suspect, then, that at least some older people do less well when they are afraid that involvement in a task involves unreasonable risk of loss or embarrassment, but that careful control of instructional set may well induce the older person to consider alternatives he might otherwise eschew.

COHORT-APPROPRIATE ASSESSMENT TECHNIQUES

Although the Wechsler-Bellevue was one test especially constructed to counter the objection to the Stanford-Binet that it was not age appropriate, little has been done to continue the search of ma-

terials that might be appropriate to the careful definition of intelligence for adults and particularly the aged. The problem here is that once again we are confusing the contribution of ontogenetic and sociocultural change to the study of age differences. In other words, a test is not inappropriate for old people because it was constructed for young adults, but rather because it was constructed for the members of a different cohort with different sociocultural exposure. Paradoxically, I suspect, the original Wechsler-Bellevue would likely now discriminate against young adults. And R. F. Monge and his associates (personal communication, 1971) have shown that it is quite possible to construct tests² at will which favor the members of earlier cohorts (also see Demming & Pressey, 1957). I am suggesting then that our findings on cohort differences call for the development of more cohort-appropriate assessment devices, carefully linked by comparative factor analysis (Nesselroade, 1970), before the conventional young-old comparisons so popular in the gerontological literature can become truly meaningful. Along these lines, we may further question whether or not the kind of techniques that appeal to young children simply on the basis of curiosity or competence motivation can have similar appeal to adults. Yet there must be many life situations that are saturated with the factors relevant to the construct of intelligence which offer rich promise to future investigators.

Implications for Social Policy

I have previously argued that there may well be a conspiracy on the part of the middle aged to remove the old from active participation in society. I suggested (Schaie, 1973d) that it is quite true that in a primitive society cumulative trauma will lead to loss of energy level and functions with increasing age, such that old age and increasing pathology, and therefore deficits, are virtually synonymous. But this relationship has in the main been broken, and we can assume that in our present highly automated society, age differences in intellectual performance, while statistically significant, may in absolute magnitude be so small as to have virtually no social consequence.

We are now ready to deduce public policy implications from what we now know about the in-

tellectual functioning of the aged. In the light of what we have said thus far it is reasonable to conclude: (a) that much of the presumed intellectual decline of the old is a myth, (b) that there are indeed age differences in intellectual performance due to different educational exposure and unequal access to life support systems required to remain at an asymptotic level, (c) that the level of intellectual functioning of those of us who will become old will be higher than that of those who are old now, and (d) that manipulation of motivational factors related to intellectual performance in the aged is feasible.

The most directly discernible consequences of this proposition seem to me to be found in the areas of adult education, the issue of variable retirement, and the question of age segregation.

ADULT EDUCATION

The evidence on intellectual performance in old age clearly suggests that people can and do function at a high level throughout life, and thus can be expected to continue the educational process into very old age. However, contrary to past practice, it is not good enough to think of "retirement skill," hobbies, and the like in planning adult education for the middle aged and aged. A consequence of our finding of significant differences in levels of functioning between generations would be the development of specific educational programs designed to reverse the cultural and technological obsolescence of the aged. I would argue that it might be highly desirable to have "Head Start" types of cultural exposure programs for today's elderly to permit them to share more adequately in our present society. Upgrading job skills for the middle aged and second- and third-career education at many life stages should be in high demand if introduced in a meaningful manner.

But this may be the crux of the matter. What we have said about the problem of cohort-appropriateness of measures of intelligence applies equally to adult education in general. We must carefully define what sociocultural skills have been missed by today's aged, and we must structure materials and instructions in ways that are appropriate for the old. For example, since we know that the old will avoid risky situations given a choice, it might well be that we have to introduce some compulsory education requirements for adults also, or alternately to set up adequate reward con-

² Unpublished experimental tests from the Syracuse adult development study.

ticiencies for voluntary participation. We must furthermore adapt current technology of information acquisition to the special problems of the old. That is, we must recognize that there is a high frequency of sensory problems in old people. Thus, special materials using large type faces, learning programs having more redundancy, and computer-aided instructional devices specially programmed for the slower response of the aged may all be needed.

VARIABLE RETIREMENT

The data about stability of intellectual performance until shortly before death certainly argue for a reexamination of mandatory retirement policies. I would like to repeat my argument here (Schaie, 1973d) that age is a totally inappropriate criterion for determining whether or not performance is adequate for a given vocational skill. But we do have enough information on age differences for various skills and their relation to occupational requirements to develop formal techniques for appraising whether or not retirement is desirable or mandatory. Such procedures have been used successfully for years in determining fitness for persons in critical occupations such as pilots. I believe that any support for a rationale that mandated retirement by chronological age because the latter was a useful predictor of the criterion of intellectual lack of competence must now be laid to rest. In fact, if we had to select a chronologically meaningful retirement age (say, using the same criteria that might have led to age 65 when the social security laws were first written), it would now have to be at least a decade later than would have made sense 20 years ago.

Even more important are the data on vast individual differences in individual patterns of development. Thus, individuals who are still engaged in intellectual growth, no matter at what age, are not ready to retire from active involvement with the work of the world, while those who are on the downgrade early in life should not be required to contribute what they no longer can provide.

AGE SEGREGATION

The evidence on the preponderance of generational variables in age differences might superficially suggest that segregation of different cohorts in their

own communities might relieve intergenerational conflicts and might permit the provision of simplified environments for the aged individuals who early in life had been able to cope well when the environment they were required to deal with did not meet the complexity currently encountered. It is, of course, desirable to reduce the complexity of the environment for all of us and to build life support systems, but the aim here should be to build complex support systems to permit well-differentiated patterns of behavior, rather than reduce the stimulation provided by the environment. It is not unreasonable to predict that more detailed analyses of an individual's microenvironments will show that maintenance of cognitive function is significantly affected by the complexity of the world we live in.

Indeed it may be argued that the difficulties encountered by the aged due to progressive cultural obsolescence can best be countered not by greater age segregation but by intervention early in life to reduce age segregation. That is, we need to rebuild our communities in ways that permit greater contact between the generations. We need to provide other than child-centered recreational and entertainment facilities. We must break the generational gaps by permitting opportunities for children and old people to interact without demanding a return to the extended family structure. Old people (and people of any given life stage) stick together not necessarily because they have common needs and concerns, but because they have had common previous life experiences not shared by others. But this fact is indeed a consequence of age segregation, rather than the justification for it.

Conclusion

We have suggested that the major finding produced in the gerontology laboratory in the area of intellectual functioning is the demolishing of the myth of serious intellectual decrement in the aged. Related to this were issues regarding risk-taking behavior and intellectual performance and the appropriateness of assessment devices in cross-cohort comparisons. From these findings we suggested that there are policy implications for many areas but specifically for revisions of thinking in the programming of adult education, as evidence for the desirability of variable retirement policies

and as evidence against the desirability of age segregation.

Translations in Gerontology— From Lab to Life

Psychophysiology and Speed of Response

JAMES E. BIRREN *University of Southern California*¹

This article states some principles and gives a perspective on research findings on aging that lie behind some of the daily life circumstances of growing old. Usually a science and real-life dialogue such as this is caught in a division between a humanistic orientation and the empirical scientific traditions or what one might call the mechanistic traditions. My proposition is simply that laboratory research on the psychology of aging is a potential friend of the aging adult and that we ought to utilize the findings of the laboratory for the benefit of an aging population.

Much of my own research and that of several of my colleagues has been devoted to the study of the differences that occur with advancing age in speed of response (Birren, 1963, 1965). The issue is, How is such research relevant to the circumstances of older persons? I believe it has several points of relevance. For one thing, older people are strikingly affected by accidents. Accidents occur to older people whether they are pedestrians, drivers of cars, or in their own homes utilizing the normal appliances in everyday life. In particular, older people hurt themselves through falls, often fatally. Sometimes it would appear that the older person lacks the speed and agility to execute an evasive action in the face of an impending accident. Sometimes the accident-avoiding action has a limiting physical quality about it; that is, the younger person would or could move or jump out of the way more quickly and thus avoid an impact. Sometimes the action also has to do with time taken to scan

one's environment and make a decision rapidly enough to take appropriate action. Observation of an older adult can suggest that attention may become sluggish and shifting from task to task occurs more slowly than for the teenager whose mind appears to dart rapidly.

I think you might agree that following an older adult driver suggests that aged behavior on the road has some different qualities than the behavior of a younger driver. In their favor it must be said that older drivers rarely drive too quickly. Offsetting this is a tendency to unpredictable behavior and making errors of judgment as to when a turn is appropriate. My fundamental proposition here is that some of these qualities of behavior shown with advancing age are intimately involved with the speed of processing information by the nervous system.

Time as a Variable in Behavior

Usually one builds up to a principle by a review of the literature; however, in view of the nature of this article I wish to state my basic proposition at the beginning, then trace its development and implications. My basic proposition is that with advancing age individuals on an average show a tendency to a slowness in response which reflects a basic change in the speed with which the central nervous system processes information. For some reason this principle seems difficult for psychologists to accept, and indeed I note my own students after spending several years in study with me sometimes miss the main point as well as its implications. The main point is that with age any event processed by the nervous system takes longer. Whereas in the young adult speed of response is usually related to such things as familiarity, uncertainty, and motivation, a limiting factor

¹ See editor's note, p. 796 of this issue. Preparation of this article was supported in part by Research Grant 93-P57621/9-01, from the Administration on Aging, U.S. Department of Health, Education, and Welfare.

emerges in the older adult, that of processing time. I would like to introduce an analogy to make my principle clear.

If in this period of energy shortages one has an electrical brown-out, one will discover that many of the electrical appliances used in the home will run more slowly. The voltage drop results in a slowness of motor-driven activities. If one considers a calculator that is running with a slower motor during a voltage drop, any process the calculator was used for, such as addition, multiplication, subtraction, or division, would be slower than usual. Large computers are often characterized in terms of their unit processing time; the faster the time the larger the capacity.

I want to go a step further to extend my analogy with respect to an aging human organism, with the expectations that I am probably right but I may be wrong. General observations suggest that the aging individual can do most if not all of the things he did when he was younger but not do them as quickly. Often there is a tendency to want to regard the quickness of behavior as not an intrinsic property. The technical sense that I am suggesting is simply that speed of behavior in the young adult is commonly regarded as a dependent variable; it depends on other circumstances surrounding the performance. In the case of the aging individual I believe that speed itself becomes the independent variable with which we must interpret and explain other kinds of behavior. This has to do with the proposition that if there is a central slowing of processing or mediation then all phenomena we regard as important in behavior will slow down. Perception and memory will become less efficient, as will retrieval from the long-term store of previously learned material. Furthermore, the likelihood of novel associations will decrease.

Young adults appear to be quick or slow in their behavior in accord with the needs of the situation in which they find themselves. On the other hand, older adults seem to have a characteristic or general slowness of behavior, an expression of a primary process of aging in the nervous system. While the precise location or the physiological basis of this slowness is not known, its consequence of behavior is becoming more apparent. Although I appear to be saying that there is a generalized brown-out in behavior with advancing age such that speed of intrinsic events of the nervous system is a limiting function, it should not be assumed from this that it had to be inevitable. As some of

my colleagues are pointing out (Schonfield and Schaie, this issue), the range of individual differences is considerable, and one might make the obvious statement that the speed of an event is not necessarily the determiner of the pleasure we derive from it.

Historical Position of Time in Relation to Behavior

Early psychologists and physiologists differed in their approach to timing of behavior with advancing age. In the second edition of Cowdry's *Problems of Ageing*, Malcolm Critchley, a neurologist, reviewed the nature of the changes in the nervous system with advancing age. He noted that there was a change in reflexes, a kind of sluggishness in response. Also he noted that with regard to motor activity "a slight generalized poverty of movement, is characteristic and is usually associated with slowness of movement, an attitude affliction in a mild state of hypertonus or—better perhaps—difficulty in relaxation [Critchley, 1942, p. 523]."

In the same volume, Walter Miles pointed out that speed of movement did appear slower in his older subjects. He tended, however, to keep separate the data on speed of motor movements and perception from the information about intelligence and age. In discussing intelligence he said,

Speed of response is . . . dependent to no small extent on the physiological equipment available for psychological perception and response and it is with interest but without surprise that we learn that when the speed factor is eliminated the coefficient of age-score correlation for intelligence during the life span of adult maturity drops from an average of .4 or .5 in various more or less homogeneous groups to .3 or less for a single somewhat heterogeneous population [Miles, 1942, p. 769].

Miles, I believe, was hoping that in partialing out speed it would leave intelligence uncorrelated with age. In fact, by so partialing time out one may be throwing out one of the most intrinsic factors of intellectual activity, speed of association. Miles, as well as other psychologists, had been embarrassed by the data on speed and aging which seemed to suggest that the older organism was not efficient when data on verbal skills showed no decline or perhaps an increase.

Somewhat earlier than Miles and Critchley, Pavlov had observed that it was more difficult to establish conditioned responses in older dogs; he generalized his observations to suggest that with advancing age the neural processes were less lively.

This somewhat metaphorical way of expressing the relationship does, however, imply that the nervous system was slowing down. An earlier psychologist, Thorndike (1928), had maintained that speed was a different property of mind along with power and attitude in the consideration of effective intelligence. Both he and his students, however, tended to neglect speed as though it were a peripheral matter. In Thorndike's day, age 45 was old, and one of his interests may have been to assure that people in their 30s and early 40s could still learn effectively. Presumably we would now move up this age considerably. Following Thorndike, his students argued that timed psychological tests were particularly embarrassing to older persons. Given a certain slowness in responding, older people will not answer as many questions on an intelligence test within a fixed time limit. By removing the time limits, performance becomes higher and presumably better reflects the true intellectual power of the individuals. Herein lies the fallacy, however. One did not know 30 years ago whether an intelligence test taken with or without time limits was a more valid indicator of that elusive quality we call intelligence. One had a tendency if one were a psychologist a generation ago to regard this speed as somehow peripheral or distant from the important qualities of the mind. In the parlance of the learning investigators, speed was regarded as a "performance factor" somehow not intrinsic to the process itself. What a strange kind of nervous system was implicitly being postulated as though the vital neural junctions leading up to the response or indeed the operation of the motor neurons in the spinal cord as well as the descending tracts from the cortex which carry the neural activity necessary in voluntary movement were uninvolved. It seems most unparsimonious to regard the operation of the peripheral neural elements as independent of the higher processes in the aging nervous system.

Magladery (1959) pointed out the effect that the higher centers of the nervous system have on simple reflexes:

The results emphasize, rather, potential prolongation of relatively low level responses when potentiation from higher centers may be diminished. In the case of mono-synaptic reflex discharge, and the processes subserved by such, this increased delay can not be of great functional significance in terms of any one motoneuron pool. When cumulative, however, and particularly when processes such as these are operative over complex spinal reflex arcs which are more dependent for excitation than single synapses on influences from higher centers, these increased

central delays may be very important indeed. They may well be sufficient to account for good proportions of the slowed motor response times in the elderly [Magladery, 1959, p. 181].

Thus, we have a rather unique situation in which the neurologist and the neurophysiologist suggest that slowness of responses becomes increasingly important as the responses involve higher centers and the psychologist wants that slowness to be restricted to the periphery and limited to such things as movement and not to involve processes of thinking. This indeed, I believe, was wishful thinking on the part of the early psychologists, when they hoped that older persons would simply be slow in their behavior but that the processes of mind remained unchanged, that is, such processes as thinking, reasoning, perception, and recall from memory. However embarrassing it may be to us as individuals, it seems that we have an obligation as objective observers to tell ourselves and our fellowmen how it really is as we grow old and indeed how the nervous system itself changes and influences behavior.

From a physiological standpoint it would appear that the more complex the behavior and the higher the level of the nervous system involved, the greater the slowness in the response with age. It is possible that a central process associated with the ascending reticular activating system might lead to the observed slowness, but it would seem to be an unrealistic position to hold that the reduction in activation and alerting would affect only the voluntary or pyramidal motor system. I would counter this line of reasoning with the observation that given a rapid decay system in memory, a sluggishness in processing information would preclude the opportunity of using decaying information in combination with other stimuli. In brief, I suggest that man is not simply a calculator that is slowing down because of an electrical brown-out, but man is a calculator that has some components that decay with time such that if the events are not completed within a time limit the possibility of the task being completed successfully is diminished. This leads us now to consider the role of diminished speed in the various adaptive capacities of the organism's perception, memory, learning, intelligence, and perhaps personality.

Perception

A variety of past as well as recent studies have shown differences with age in perceptual functions,

particularly vision. For example, it has been known for quite some time that the flicker fusion threshold increases with age. That is, a flickering light is regarded as a continuous light at a lower frequency by older subjects than by younger subjects. This suggests that the neural events may not be quick enough to allow discrimination of the series of events (Weiss, 1959). More recently this has been shown elegantly in a perceptual masking experiment by Donald Kline (1972). In his study of monoptic visual masking, a second stimulus defined as visual noise followed the first stimulus by a variable interval. The effect of the blocking or masking stimulus occurs at longer intervals for the older individual. It was also shown that in order to be perceived, the minimum exposure time of the initial or target stimulus was longer for the older subjects. One is left with dual phenomena in which the excitation corresponding to the initial stimulus takes a longer time to reach its maximum effectiveness as well as to decay, as shown by a longer masking interval. Both of these findings suggest some loss either in Pavlov's terms of neural liveliness or speed of neural events with age.

If one begins with the notion that neural events are slower with age and uses this as the explanatory independent variable, then the perceptual phenomena would be subsumed as part of a slowness in general processing time.

Memory

Not only are perceptual processes likely influenced by a slowness in central nervous systems processing, but memory also. In 1965 I reported some limited data on the relationships of tests of memory to measures of speed of writing digits. An important result in the present context was that the correlations between the Wechsler Memory Scale and speed in young subjects was not significantly different than zero. In fact, it was $-.01$. In elderly subjects, that is, those over 60 years, the correlation between the Wechsler Memory Scale and speed of copying digits was $.52$. While the content of the Memory Scale may be difficult to define in the context of laboratory learning studies, it does indicate that with older adults the intercorrelations between speed measures and such tests of memory increase.

More recent studies of memory in the context of verbal learning (Johnson, 1973; Robertson, 1972; Schonfield & Robertson, 1966) indicate that

the largest difference with age in memory functions is not in the storage of information but in retrieving it from store. It is shown that recovery of information from long-term storage is best done by recognition rather than by total recall. Furthermore, Johnson's experiments showed that cued recall benefits disproportionately the older person. While it is premature to directly implicate an effect of slower central processing time, it is not premature to speculate about its role.

One possibility is that if neural events are indeed slow, the scanning of currently presented information and information from long-term store may be slow. Under these circumstances the individual may show a decreasing probability of eliciting the appropriate material from long-term store and the high probability of distraction. The set or search criterion may decay during a protracted process of retrieval. Robertson (1972) in her studies indicated that older subjects do retain material but frequently will allow this material to intrude as inappropriate associations; that is, memory itself is less affected than its retrieval at an appropriate time. An alternative interpretation is that older subjects do not employ mediating processes to the same extent as young persons. Under this circumstance the aged are disproportionately aided when cues are supplied to them because they do not themselves tend to use cues in both the original learning and perhaps in the recovery from the memory store. Further research in this area is needed to either refute or substantiate the role of speed of central nervous system processing in both primary and secondary memory processes and in scanning and retrieving. The proposition being favored here is that the primary change is in speed of neural events which influences memory. Put in other terms, we do not remember because our associations are slow, not that we are slow because we cannot remember.

Learning

Presumably, if perceptual and memory processes are influenced by changing central information processing, then learning itself must be influenced. Considerable research has been devoted to the issues of pacing in learning. Results indicate that older subjects should be given longer intervals between stimuli to elicit a response. If crowded by short intervals, they failed to respond, and one notes a rise with age in omission errors rather than

commission errors. This recently has been brought into question by Robertson's work which indicates that both errors of commission and omission occur. Apparently whether one commits more or less errors of commission is a function of the particular experimental context.

In learning experiments the issue may be discerned as to whether older subjects want more time or need more time. Given the interpretation that they are cautious and seek more certitude before they respond, they want more time. Taking the interpretation that the central processing time is limited, then they need more time. In the case of perceptual and memory processes it would appear to the writer at least that the older individual needs more time rather than wants more. In the case of learning the situation is not so clear-cut. One of the uncertain areas is how to interpret the evidence that the older individual is relatively better in incidental learning than in directed learning (Johnson, 1973; Wimer, 1960). The fact that older subjects have a more difficult time in intentional or directed learning would suggest some difficulty in controlling attention or set. Thus, in the learning situation the older adult is taking in too much information and therefore cannot concentrate on crucial information most relevant to the task. Here one can point out that some very illuminating experiments could be carried out at the present time on relationships between attention processes and speed of information processing in relation to learning and age. Given a change with age in the central nervous system such that information processing is slower in all aspects, then attention itself should not be spared. Indeed, the establishment and maintenance of a set should be more difficult in the older individual. There is in fact some evidence for this in the reaction time studies of Botwinick (1957). He found that for expected stimuli, set is more difficult to establish and maintain in the older individual. Future research should be directed at the relations of slowness in CNS function with age and attention.

Motor Skills

Considerable research from the Cambridge Laboratory established the fact that the greatest difference between young and old adults in slowing of motor skills occurred at decision points. That is, movement itself was not so much changed with age as was the redirecting of movement in response to

new information (Welford, 1959). This of course fits the earlier expressed idea that the higher one goes in the centers of the nervous system the more the slowing becomes evident. While repetitious movements such as tapping are slower with age, it is in the redirection of movements that the additional time is taken (Rabbitt & Birren, 1967). Thus sequential tasks that require intervening decisions are disproportionately lengthened with age in contrast to simple repetitious movements. This of course fits the thesis that the change in central processing time is the critical one with advancing age.

Intelligence

Much of the newer research findings on intelligence with age are showing significant cohort differences or differences between the generations in intelligence. Indeed the review by Schaie (pp. 802-807, this issue) amply documents this. Nevertheless, despite the large differences in cohorts there is still a difference between verbal tests and those involving perceptual speed, the latter still showing decrements in an older population. The study of healthy older men at the National Institute of Mental Health reported differences in both speed measurements and on nonverbal intelligence measures such as the Raven Progressive Matrices, in contrast with vocabulary and information tests (Foulds & Raven, 1948). Horn and Catell (1966) commented about the fact that crystallized intelligence representing the store of information acquired over time continues to rise with age whereas fluid intelligence, a more dynamic catalytic cognitive property, declines. Schumacher (1970) emphasized these points and drew inferences about altered physiology of the nervous system that may account for this. It would of course fit the hypothesis advanced here that fluid intelligence should decline because it would represent a decline in the rapidity with which one can scan stored information and recombine it with current input for a needed and perhaps novel response.

Earlier research by Chown (1961) in which she correlated tests of rigidity with age and with intelligence indicated that with advancing age there was a tendency to show greater rigidity. It was difficult to interpret the rigidity outside of the context of cognitive functioning itself; that is, the central change may lead to cognitive deficit and to the apparent changes in rigidity. In this sense,

then, rigidity may be less a personality predisposition or a reversible set but rather a required difference in behavior due to the changes occurring within the nervous system itself. That is, many older individuals do not want to be rigid but are rigid because of a necessary consequence of the way the older nervous system functions.

Timing and Its Relation to Neural Activity

One of the current dilemmas is how to interpret the tendency for older subjects to show a lowered alpha frequency with advancing age (Ohrst, 1965; Thompson & Marsh, 1973). Surwillo (1963) interpreted this as reflecting a change in the basic timing in the nervous system and, in fact, regarded the alpha frequency as a pacemaker of behavioral processes. Subsequently, the biofeedback conditioning experiments of Woodruff (1972) indicated that to some extent one could reverse the drift toward lower frequencies of alpha in the older subject by appropriate biofeedback conditioning and this would be correlated with the faster timing of responses. While the correlation between response speed and alpha was significant, the data suggest that most of the variance attributable to the relation between age and reaction time is unexplained by the change in alpha per se. Nevertheless it does show a linking in speed of response with neural activity.

Eisdorfer (1968), in his experiments with learning and autonomic nervous system activity, has emphasized that with advancing age there tends to be an overarousal of the sympathetic nervous system or, more particularly, increased activity of the peripheral autonomic end organs. This would seem to lie in contrast with the hypothesis that the central nervous system was showing a quality of underarousal. The unpublished evidence of Jeffrey shows that older subjects will improve their speed of response given amphetamines or stimulating adrenergiclike drugs. There remains considerable uncertainty as to the relative contributions of central versus peripheral sympathetic effects on age changes in behavior. Earlier, Birren (1963) reported data which indicated that elevated blood pressure was associated with slowness in response, thus a balance of central nervous system activity and peripheral autonomic activity was implicated. Increased sympathetic activity may reflect a relative inhibition or underarousal of the central ner-

vous system with regard to facilitation of perceptual and motor responses. Thus the issue that older subjects on the average may show increased sympathetic activity may not in itself deny the possibility that there is a concomitant slowness in central information processing.

Implications of Data on Timing, Behavior, and Aging

For a considerable period of time behavioral data on aging appeared to be very compartmentalized, and very little thought was given to the possibility that there were any major common underlying processes. More recently, however, there seems to be recognition of the fact that with age there may be some general changes in behavior due to common processes. An important study was carried out in the Netherlands using 150 psychological and physiological variables (Dirkin, 1972). The measurements were obtained on 316 male workers in Dutch industry. Of interest was the fact that the cluster analysis of the main variables included psychological as well as physical variables. Investigators concluded, "This can be considered as an indication that the somatic and mental aspects of aging are highly interdependent, it even confirms that aging is controlled by a general process, influencing all subsystems simultaneously [Dirkin, 1972, p. 209]." With this encouragement one may regard the changes with age in central processing time as the major independent variable in explaining much of the behavioral changes with age. However, the timing itself becomes dependent on other physiological phenomena, particularly its relationship to somatic disease. As mentioned earlier there is a correlation between slowness of response and blood pressure such that the higher the blood pressure the slower the response. Also subjects with cardiovascular disease show a disproportionate slowing in information processing relative to others their age. One of the more recent developments in this area is linking slowness of response to predisposition to cardiovascular disease.

Rosenman has established the association of a personality style with the likelihood of developing cardiovascular disease, specifically coronary artery disease (Rosenman, Friedman, Jenkins, & Bortner, 1968). Subjects who show a constellation of time pressure, restlessness, responsibility, and many diffuse goals have a much higher likelihood of developing coronary disease than individuals who are

not so time pressured. Taking this evidence as a point of departure, Abrahams (1972) studied a group of young adults and classified them according to their predisposition or nonpredisposition to cardiovascular disease. Reasoning that later in life slowness of behavioral functions is related to cardiovascular disease, he thought that individuals early in life that were so predisposed would show slowing. Indeed, his results do bear this out. The fact that the reaction time of subjects in their early years who are predisposed to coronary heart disease is significantly slower than their nonpredisposed peers would indicate that there is a common basis for the predisposition to cardiovascular disease and the timing in the central nervous system itself. Slowness of information processing with age is an issue directly involved in questions about the basis of somatic changes with advancing age.

The data on slowness of reaction time with age have direct implications for how older adults can manage themselves in their environment. While response times of young adults may be slow or quick depending on the demands of the environment, older adults are slow as a general feature of their behavior. Furthermore, since disease is intimately related to the slowness shown by older adults, the view is advanced that while age appears to be accompanied by normal psychophysiological slowing it is exacerbated by the presence of disease, particularly those diseases of a stress character and involving the sympathetic nervous system.

Summary

One application of available information is that we may begin to attempt to identify individuals early in life who are predisposed to coronary heart disease by behavioral assessment. Subsequently, by suitable conditioning it may be possible to minimize the coronary risk that these individuals are to incur. Psychology would appear to have an important contribution to make to the early detection and management of somatic disease.

Research results to date have clear implications for the design of the environment to maximize the potentials of the older adult. One of the largest areas of potential contribution of psychologists is likely to be in the management of accidents, which are so disastrously high in frequency for older adults. Evidence suggests that it is not so much the motor response or muscular strength itself which leads to accident-prone behavior in the aged

but rather slowness of decision times and the inability of the older person to rapidly discriminate relevant information from irrelevant information. Automobile accidents and pedestrian accidents often imply failure of judgment. One may speculate that the time taken to scan traffic flow, traffic lights, and other information and to arrive at relevant decisions at an appropriate time is often not possible given the timing characteristics of the older nervous system. A pacing of environmental events which is appropriate for the 25-year-old is not appropriate for the average 75-year-old to permit effective behavior. Time and pacing of the environment, particularly an urban environment, are commonly hostile to optimum adaptive behavior of the older person. While the environmental principles that are sound for older adults may also be sound for young people, such as minimizing irrelevant information and maximizing relevant information by important judgments, the basic issue of time itself is not readily resolved. That is, safe street crossing by an older pedestrian may require twice the length of time that it will for a young adult. Given the impatience of motorists, the young drivers' timing and the timing of young pedestrians dominate the present scene. The urban microenvironmental situation is harried for the older adult, and time itself is a key element.

As a point of departure for further research on the older nervous system I can think of no greater vantage point than studying speed and timing. Such information has prospects for considerable scientific gain in understanding the organization of behavior and for the design of an environment that will be supportive of older adults.

Token Rewards May Lead to Token Learning

FREDRIC M. LEVINE *State University of New York at Stony Brook*¹

GERALDINE FASNACHT *State University of New York at Stony Brook*

In the past 10 years or so clinical psychology has, with great pride, increasingly embraced the operant tradition of experimental psychologists. Behavior modifiers have learned and demonstrated that a wide variety of behaviors can be changed by the application of operant procedures in clinical settings. We have been involved in and read about the vast changes of schizophrenic behavior on a ward, children's temper tantrums, seizures, etc., by the judicious application of contingent reinforcement. It is clear that reinforcement works and that an operant analysis of behavior provides a powerful and useful tool for clinical intervention. By changing contingencies, the therapist can often produce rapid changes in disturbing behaviors.

Many programs have been using "token"-type programs to produce behavior change. The usual paradigm of these programs is to give the subject some material reinforcer for a predetermined response. Sometimes the reinforcer is a token or a point which can later be turned in for a prize of some sort. A child may, for example, earn 10 points in a week for completing his daily homework. At the end of the week he can trade these points for a desired toy. For the purposes of this article, we treat token programs as those that use reinforcers for predetermined responses.

Because of the dramatic success of token approaches and because of their relative simplicity, there is a growing tendency to utilize these approaches in more and more settings. Both education and industry seem determined to squeeze more "appropriate" behaviors out of their populations

by reinforcing the "right" response. The gold star and the key to the executive toilet will be issued immediately only after the appropriate behavior is emitted.

There are numerous examples of this recent rush into the use of token reinforcers. Research Media, for example, is advertising a course in the use of tokens which can be used for, among other things, "improving both quantity and quality of academic performance. Coping with behavioral problems. Increasing productivity. Enhancing interpersonal relationships. Motivating personnel. . . ." Patterson and Gullion (1971), in a widely used manual for parents and teachers, advocated the use of token procedures to eliminate the negativism of "the 'I don't want to' child," to quiet "the overly active, noisy child," and to calm "the frightened child." A recent paper (Hauserman, Walen, & Behling, 1973) demonstrated that a token system (while in effect) increased racial integration of first-grade children. Although the immediate effect of these programs may be positive, we have trepidations about the long-range value.

Based both on theoretical considerations and on practical experience, we feel that token approaches will do more harm than good when applied in what is an increasingly promiscuous manner. In the words of the unacceptable medical model: The cure may be worse than the disease.

Within the experimental-behavioral approach, there is another growing tradition: the cognitive approach of attribution theory. Attributional theorists claim that how we attribute the causality of our behavior will in turn determine future behavior. Whether we perceive we are doing an activity for pay or for joy will influence how highly we will value the activity. An impressive amount of data from attribution type research has accumulated which indicates that giving a reward can have an effect counter to that desired. Giving points, tokens, M&Ms, etc., to a child for learning a lesson

¹ The authors wish to thank Marvin Levine, Marcia Johnson, David Pomeranz, Dana Bramel, and Leonard Krasner for their helpful comments and criticisms.

will decrease the intrinsic satisfaction of the lesson. The first author, while in his uncritical operant days, had the rare experience of watching his five-year-old son keep his room tidy for several days. In the best of operant traditions, the author gave his son a toy as a reward for tidiness. Not only was the room never voluntarily cleaned again, but a reward was demanded for many other once-routine responses: "Will I get a reward if I give you a hug?" etc.

Most college students like Soma blocks, a puzzle of various shaped blocks which, if correctly placed, can be made into certain shapes. Deci (1971, 1972) found out how the fun can be taken from the blocks. He asked students to manipulate the Soma pieces to reproduce four configurations that had been drawn on paper for them. If the subject could not solve a puzzle in the 10 minutes allotted for each configuration, the experimenter stopped him and explained how to do it. After completing the puzzles, the subject was left alone in the room for 8 minutes; he was free to do anything he liked, for example, read magazines or work on the puzzles. Intrinsic motivation was measured by the amount of time the subject spent working on the puzzle. Half of the students were told at the beginning of the experiment that they would receive \$1 for each correct solution and, therefore, a maximum of \$4 if they solved all of the puzzles correctly. The other half of the students were not promised any rewards. Those students who were paid spent significantly less time working the puzzles during the 8-minute period when they were left alone than did those who had received no reward for doing the puzzles.

Lepper, Greene, and Nisbett (1973) used an educational setting to assess the effects of extrinsic reward on preschool children. The amount of time children spent at a drawing activity while other activities were going on was used as the measure of intrinsic value of the drawing. Lepper et al. used three groups of children. One group agreed to perform the drawing activity for a reward certificate. A second group took part in the same activity without prior expectation of reward although they were rewarded after the task. The no-reward control group neither expected nor received a reward. Experimental sessions were conducted outside of the classroom. The expected-reward group showed less interest in the activity when it was available in the classroom at a later time. The paradox again emerged in which rewarding a response led to a decrease of the response when the

reward was withdrawn. In addition, interest increased slightly in the group that did not get any reward. Lepper et al.'s conclusion was that token economies, and extrinsic reinforcement in general, tend to undermine interest in those cases in which interest is already at a high level.

Kruglanski, Alon, and Lewis (1972) studied the relationship between external rewards and task enjoyment. The 10-11-year-old members of winning teams in a series of group competitions (Follow the Leader, Word Construction, Song-Matching, Discover the Rhyme, Speed Writing) were either rewarded with a prize or received no prize. The prize group had not received an initial promise of a reward. Later the children responded to questionnaires about their enjoyment of the games and their reasons for participating when other activities were available. The prize group rated their tasks as less enjoyable than the no-prize group. Those children who said they had performed the task for a prize enjoyed the tasks less.

In another study by Kruglanski, Friedman, and Zeevi (1971), one group of 15-16-year-olds was offered an extrinsic incentive for performing several recall and creativity tasks. The incentive consisted of a visit to the psychology department, a reward that had been previously determined to be attractive to the subjects. A second group was not offered an extrinsic incentive. Not only were recall and creativity higher in the no-incentive group, but ratings of task enjoyment were also higher for the no-incentive group as compared to the extrinsic-incentive group. A higher quality of both performance and motivation was found in the absence of external rewards.

Data on unexpected rewards have shown conflicting results. Kruglanski et al.'s (1972) unexpected-prize group rated their tasks as less enjoyable than the no-prize group. On the other hand, Lepper et al. (1973) found that children in their unexpected-reward group displayed an undiminished or increased interest in the drawing activity. As yet, no conclusions can be drawn from the data. If unpromised rewards should be found to have an incremental effect on interest, the effect cannot be repeated often: An unexpected reward is only a surprise the first time it is used.

As applied to token economies, the results of these studies indicate the trepidations the practitioner should have before instituting a token program. There should not be an attempt to use external rewards for behaviors that are of some intrinsic interest. If children are engaged in class-

room activities, adding rewards for learning should have the effect of increasing the learning while the rewards are used. However, the longer range consequences of using external rewards for responses that indicate interest in the activity are clear. The token rewards will lead to a decrease in interest.

An attributional explanation is often given for the finding that the intrinsic pleasure of an activity can be reduced by giving extrinsic reward for the activity. The attributional explanation (Bem, 1967) usually is in the form of the following: If one is doing activity X without a reward, then activity X must be worth doing. If one is getting a reward for activity X, it must not be worth doing without the reward.

However, in 1950, Gately, one of Harlow's master's students, reported results in monkeys which were startlingly similar to the "cognitive" findings. In the now famous hasp and latch puzzle (which led Harlow to question traditional drive reduction theory), there were two groups of monkeys. For one group the puzzles were baited with raisins; for the other group there were no food rewards. The rewarded group as a whole performed better than the manipulation-only group. More importantly, the unrewarded monkeys continued to display interest in the puzzles throughout the testing session while the rewarded monkeys lost interest in the puzzles as soon as they removed the food. Again, the group of monkeys who did *not* get food as a reward for solving the puzzle was the group who played with the puzzle with undiminished interest. Perhaps attentional variables are the key. Reinforcement may shift attention from the activity to the reinforcer.

The applied implications of the above research are clear. In our haste to demonstrate that learning can be increased, productivity raised, and manners improved, we operant-oriented therapists may, in the long run, be decreasing the frequency of the very behaviors we wish to increase.

Another question of considerable interest is what happens to those reinforced behaviors after tokens are withdrawn? What are the long-range consequences of the use of tokens? The hope was that tokens would "prime the pump" and allow natural reinforcers to take over after the desired behaviors were well established. It was expected that generalization would take place. Despite this hope, there is little acceptable evidence for tokens having this desirable effect. There are some recent claims that generalization exists (Cohen & Filipczak, 1971; Drabman, Spitalnik, & O'Leary, 1973; Patterson

& Reid, 1973). Cohen and Filipczak (1971) found an initial drop in recidivism rates for their group of juvenile delinquents in the first year after a multipronged training program which included token reinforcement, programmed instruction, and individual academic help. Because of the multipronged approach, it is difficult to ascribe the reduction in recidivism to the tokens. In addition, the data indicated that the recidivism rates would be at the level of other juvenile delinquents within three years. Patterson and Reid (1973) claimed generalization over time in improvements in the behavior of aggressive children. Global evaluations obtained by telephone calls to the parents after termination of treatment indicated marked improvements in the children's behavior. In the absence of a control group, and without independent verification of the telephone procedure, the data cannot be considered as reliable evidence for generalization. There are several recent studies which indicate that responses generalize to non-reinforced situations. Since generalization is ascribed to a failure to discriminate differences between situations (Rachlin, 1970), it is important that demonstrations of generalization be of some duration. Craighead, O'Leary, and Allen (1973) claimed generalization which persisted several days. This is not sufficient evidence for such a clinically important conclusion. O'Leary, Drabman, and Kass (1973) concluded that after an effective token program was withdrawn in a special classroom, the appropriate behavior was maintained during a 20-day follow-up period. The authors reported a reduction from an average of 1.27 disruptive behaviors per 20-second interval to an average of .54 during the token program. An average of .56 disruptive behavior occurred during the follow-up. Although these figures seem to indicate generalization of appropriate behavior after the tokens were removed, a closer inspection of the data indicates that the greatest reduction of disruptive behavior occurred before reinforcers were used, during the initial baseline period. Possibly due to observer effects, the level of disruptions at the end of the baseline period did not appear to differ greatly from that during the token program and subsequent follow-up. In addition, there was no significant generalization of the appropriate behavior to the regular classroom.

Token programs that have been in effect in either the mornings or afternoons have not shown generalization to the part of the day in which tokens are not used (Becker, Madsen, Arnold, &

Thomas, 1967; Kuypers, Becker, & O'Leary, 1968; O'Leary, Becker, Evans, & Saudargas, 1969).

Krasner and Krasner (1973), for example, stated that changes in behavior produced by tokens have not demonstrated generalization to stimulus conditions in which there are no tokens.

Behavior changes have not been maintained over time after "tokens" were withdrawn. O'Leary and Becker (1967) contacted the new teachers of children who had been in a token program the year before. Although the children displayed less disruptive behavior than prior to implementation of the token program, the frequency of such behavior was clearly greater than it had been during the token program. O'Leary et al. (1969) found that the frequency of disruptive behavior during a four-week follow-up was not substantially lower than during their "praise and ignore" phase of the program when tokens were not used. Walker, Mattson, and Buckley (1969) reported that their three- and six-month follow-ups indicated that changes in task-oriented behavior were not maintained when the children were returned to their regular classrooms. In fact, the school district asked for help the following year with 5 out of the 11 children who had been in a token program the year before. Lovaas, Koegel, Simmons, and Long (1973) found that behavior of autistic children regressed after treatment.

However, there should be no surprise that disruptive behavior bounces back when the tokens are removed. Removal of tokens constitutes an extinction operation, not a generalization paradigm. Subjects are simply being taught how to earn tokens. In a typical operant laboratory experiment, rats stop pressing the lever in a Skinner box when the food pellets stop coming. Why? The rats have learned how to earn pellets. They have not learned to value pressing the lever. In the same way, children in a token economy classroom are simply being taught how to earn tokens. Therefore, when the tokens are removed it is hardly surprising that disruptions recur. Once the tokens are removed, the children are on an extinction schedule.

Experimental psychologists have shown us several procedures for increasing resistance to extinction, for example, intermittent reinforcement, delay of reinforcement, giving noncontingent reinforcement during extinction. It is possible to use these procedures with tokens to increase resistance to extinction. Drabman, Spitalnik, and O'Leary (1973), for example, were able to obtain generali-

zation of appropriate classroom behavior in disruptive children to nontoken periods by using a procedure which involved administering tokens for 45 minutes each day and randomly selecting 15-minute control periods during which no tokens were dispensed. However, once we start instituting various ways of increasing resistance to extinction, we are making our programs more complicated and less practical. Nevertheless, an extinction paradigm by another name still smells like an extinction paradigm.

Therefore, once token-type programs are instituted, it may never be possible to fully withdraw tokens without the behavior going at least back to baseline. Furthermore, since tokens tend to decrease the intrinsic value of an activity, they may actually do more harm than good.

We do not mean to imply that an operant view of behavior is not a useful way of dealing with behavioral problems. Unquestionably, operant approaches have real value in helping to treat those populations, such as children and inpatients, in which the therapists can have reasonable control over the environment. In nine years of clinical work with such populations, it seems that the operant view is most effective in those instances when inappropriate behavior is inadvertently being reinforced. Sometimes we may be surprised about what the reinforcer is. We have seen several children whose behavior is reinforced by an angry, punitive response by the parents. So many parents yield to temper tantrums, chase children who run away, give into violence, whining, and insults that we behavior modifiers need not fear unemployment. An operant analysis often allows the clinician to change the consequences of the behavior so that disturbing behavior is not reinforced while incompatible appropriate behavior is reinforced. A child who gets attention by nagging is often one who is ignored while not annoying his parents. There is no doubt which of these behaviors will increase. We can use our knowledge of operant procedures to help rearrange the distribution of parents' attention and cookies so that we can be genuinely helpful. Tokens were not necessary for the acquisition of problem behaviors nor for their maintenance; we should, therefore, first search for the "natural" reinforcers of problem behaviors as a significant point of intervention. However, we must also use information gained in the cognitive tradition. The time has come for us to avoid a narrow operant perspective. Operant procedures have their place and their dangers.

Because of the danger that use of tokens will decrease the intrinsic satisfaction of activities, they should be avoided unless there is a real danger to the person or there is no alternative; for example, a child with renal infection and poor urinary training would justify a token-type approach to avoid a fatal renal infection. If a behavior is of low base rate and its occurrence is important, token approaches may have to be used. Hospitalized psychiatric patients who are not toilet trained, for example, place great tension on staff, who in turn get angry at the patients. A general increase in quality of recognition by others will occur when the patient does not stink of feces. The tokens may have to become as much a part of the daily schedule as are meals.

Before extrinsic reinforcers are used, however, the therapist should seek ways by which the intrinsic value of the activity can be increased. As pointed out by O'Leary and Drabman (1971), teachers should look at the interest level of the curriculum before looking to reinforce learning of material that kids just do not like. Industry should view job satisfaction in a variety of ways before using token approaches. For example, Herzberg (1968) stressed that workers need to be useful and to have some autonomy over their activities. Adams (1963, 1965) pointed out the debilitating effects of inequity. The focus with these "normal" populations in which there is not impending danger should be in making the work more intrinsically satisfying. By automatically giving tokens for tasks, although the task will be completed, there is the risk that the intrinsic satisfaction of the task will be decreased. Tokens do lead to powerful learning, but the learning may, in fact, be token.

An Overview of Psychology's Human Resources

Characteristics and Salaries from the 1972 APA Survey

C. ALAN BONEAU *American Psychological Association*

JANET M. CUCA *American Psychological Association*¹

Several major issues involving the existing supply and the production of psychologists are of current serious concern. For example, a real prospect exists that academic jobs in departments of psychology will constitute a smaller job market than has recently obtained for new PhDs. This fact of life complicates the current concern to increase the numbers of women and minority group members on faculties and in the profession generally. As a basis for planning, information is needed about the availability of minority group members and women and about the distribution of ages of current academicians. Also required is a hard look at available supply information as a prelude to a reconsideration of training goals and recruiting practices. Of interest is the fact that the employment problem may be ameliorated by the increasing tendency of psychologists to be employed in social problem areas as a result of public policy efforts at the federal, state, and local levels, for example, in health programs and in criminal justice reform. The imminent phaseout of federal funding for training, however, raises questions about the long-run availability of psychologists for public service positions.

These issues pose critical problems for individuals who make decisions affecting the field of psychol-

ogy—deans and department chairs, agency heads, Congressmen, and Congressional staff members—and for students who are making career choices. Information needed for these many interest groups includes the numbers of available psychologists at various degree levels; the fields of their expertise; their geographic, age, sex, and race distribution; their range of salaries; the number of individuals currently receiving training, and much more.

This article, part of a series of analyses of different aspects of psychology's manpower, takes a broad look at the total manpower pool in an attempt to capture the global outline: its present characteristics, the information specified above, its trend over time—past and future. Further reports will deal with major psychological enterprises such as human service, education, and research. Data for these analyses will come from many sources, but principally from the APA Manpower Data System to be described below.

From 1954 to 1970, the APA cooperated with the National Science Foundation (NSF) in the production of a biennial census of psychologists, the psychology portion of the National Register of Scientific and Technical Personnel (NRSTP). After the 1970 canvassing, the NSF terminated funding for the National Register program and attempted to develop alternative sources of information on the overall scientific manpower pool in the United States. Involving much less detail than the Register and with insufficiently large samples for most special breakdowns, these plans were viewed by the scientific disciplines as largely unsuited for their specific purposes. Consequently, the American Psychological Association, acting independently and using its own resources, decided to expand its man-

¹ The first author is Director, Programs and Planning, of the American Psychological Association; the second author, Staff Assistant and proprietor of the Association's Manpower Information Clearinghouse.

Nancy Turck provided much appreciated assistance in the preparation of the tables.

power survey activities. A few other disciplines such as physics and chemistry chose a similar course. The APA effort, in the interest of economy and efficiency, was planned as a systematic program to interlock its membership files, information for inclusion in its biographical publications, and needed statistical information on manpower. The system as developed has been described by Willette (1972).

In the spring of 1972, APA mailed an extensive questionnaire to its total membership (35,361)² and to another 26,556 nonmembers selected primarily from the membership rolls of other psychological societies and associations but also including graduate students. The final return included responses from 27,371 members (a 77% response rate) and 7,990 nonmember respondents who were eligible for membership in the APA (out of a total 10,785 nonmember responses). This report provides a summary of data compiled from those returns.³ For comparison purposes, it is in part cast in a form that resembles previous reports on psychologists in this Journal that were based on past NSF National Register data (Boneau, 1968; Cates, 1970; Cates & Dawson, 1971; Compton, 1966; Lockman, 1962).⁴

² This total includes individuals who were members at the beginning of 1972 as well as those who were elected to membership during 1972. Data are primarily from early 1972, but the new members provided information in the fall. Thus, in summary, we were considering individuals who received their degree in 1972 or earlier.

³ The representativeness of the responses has been discussed elsewhere (Boneau & Cuca, 1973). For members, the response data have a statistically significant but seemingly trivial underrepresentation of nondoctoral individuals. Outside data lead to an inference, currently unsubstantiated by statistics, that the sample overrepresents human service providers and underrepresents the academic-research sector to a small but unknown degree.

⁴ Notable differences between National Register and APA data, however, are disguised by such an approach and should be highlighted. First, the questionnaires and individual questions themselves were different, the APA version being specifically tailored to the problems arising in the description of psychologists. Second, the populations and probably the sample characteristics were subjected to unknown warpages resulting from several factors, but notably two: (a) the APA data were collected in collaboration with the Canadian Psychological Association and the Corporation de Psychologie de Quebec in order to create a "Consolidated Roster" of North American Psychologists, and (b) the participation of APA members in the APA survey was greater than in NSF canvases due, it would seem, to the tie-in with entries in the APA *Biographical Directory*. Other differences will be noted in passing. Qualifications for inclusion in the NSF Register and in the

Because of equality-of-opportunity considerations, sex and race information have become important characteristics of the manpower pool. A significant departure from previous reports will be the inclusion of racial and ethnic identification. Many analyses, previously mute about sex, will provide sex breakdowns, particularly salary tabulations. Also, because of collaboration with the Canadian associations in gathering data, we have tabulated citizenship as a characteristic.

The most meaningful comparison of present data with that of the past is based upon the total sample—member plus nonmember data—because the National Register was not limited to members of the APA. In view of the expense involved in acquiring nonmember data, however, it is unlikely that it will prove feasible in the future to acquire nonmember information from APA resources on a regular basis. Future comparisons probably will be among data gathered from the membership of the Association. Thus, for the purpose of presenting a baseline for future member data comparisons, in addition to the presentation of the total sample data we have chosen to present some data on APA members only.

Having reviewed the somewhat mundane technicalities necessary to introduce the data, we are now in a position to review it. The initial summary of data is in a form similar to that of previous reports on the National Register, a simulated National Register report, if you will. This summary presents the numbers of psychologists in the respective samples having specified characteristics. Then there is a brief review of trends since the first Register in 1954. Then we take a closer look at the current (1972) APA membership, considering the educational level and the sex of the respondents as primary variables for comparisons. Initially the analysis concerns itself with the numbers of psychologists with various characteristics, and salary data are later presented. Then appears a short presentation of data on the employment patterns of APA members. Finally we engage in a brief discussion of the numbers of psychologists and the legitimacy of the APA as a voice for the totality.

present APA compilation, however, are the same, namely APA membership or putative eligibility for membership. These qualifications for membership are a doctorate in psychology or a master's in psychology plus one year working in the field.

* N is the number of full-time-equivalent psychologists.

* The number of years since highest degree awarded.

The 1972 Simulated National Register

The first presentation of the data, in Table 1, depicts the numbers of psychologists having various demographic and other characteristics. The table contains separate columns for members, eligible nonmembers, and the total of the two columns, the latter figure corresponding roughly to the sample from previous National Registers.

Note that the total number of respondents in each column is given at the beginning of the table, as *Total*, the figures 27,371, 7,990, and 35,361 for members, nonmembers, and total, respectively. In the body of this table, as in all tables in this report, the numbers responding to any particular item will not, in general, add to the grand total. Respondents discriminated among items for which they provided information. Percentages are based on the total responses to each particular item. A few of the highlights follow:

- Seventy-eight percent of the membership in the sample holds the doctorate. By level of highest degree, however, the eligible nonmembers are distinctly different from the membership of the Association with respect to the proportion of doctorates.

Further light on this discrepancy is shed by years of experience. Over half of the nonmember psychologists have four or fewer years of experience since obtaining the highest degree. Furthermore, other data indicate that about 1,500 of the member-eligibles are still in graduate school, presumably working toward the doctorate. Clearly, the eligible nonmembers are a younger, less experienced group of psychologists consistent with a well-established tendency for young psychologists to take a few years before joining with their cohorts in supporting and identifying with the Association. Overall, however, 69% of the respondents possess the doctorate.

- The membership is primarily male: 76%. Overall the sample is 75% male, the difference being attributed to a higher proportion of females in the eligible nonmember portion of the sample.
- Of those reporting a subfield, the largest number are in clinical: 33%. The cluster of human service subfields—clinical, community, counseling, and school—comprises 56% of the total sample.
- Fifty percent of the respondents in the total sample are employed in institutions of higher education, and an additional 12% are employed in

precollege settings. Although the preponderance of psychologists are identified with human service subfields, employment in traditional human service settings is not the rule. Only 16% of the members sampled are employed in hospitals and clinics, and an additional 7% are employed in independent or group practice. The corresponding figures are 15% and 6% for the total sample.

- The largest single source of support for employment is state governments, comprising 38% of the total sample.

- As has frequently been observed, the employment settings of psychologists are predominantly in the public sector, including nonprofit organizations, with 85% of the total being so employed. The remainder are employed in private-for-profit settings (industry, etc.) or are self-employed.

- As a profession, psychologists spend the largest proportion of their effort in application and practice and the least in research, with sizable portions of teaching and management included.⁵ The balance among the four major classes of activities is to be noted. In another way of looking at activities, about 75% of the respondents indicated that at least some time was spent in each of the four major activities categories.

- The median number of years of experience of the member sample is 8.4. For the total sample there is a much more pronounced mode at the 1- and 2-year level, and the median number of years of experience for this group is 7.0. In 1972, almost half of all respondent psychologists had received their highest degree in 1965 or later!

- The distribution of ages throughout the middle range of the membership sample is reasonably uniform, and it can be clearly seen that the eligible nonmembers are a youthful group. As for medians, that of the membership sample reporting is 41.6 years; 40.0 for the total group.

⁵ The NSF National Register questionnaire asked respondents to specify a single primary work activity. Our knowledge that psychologists engage in many activities prompted us to revise the APA work-activity question to provide estimates of time percentages spent by our respondents in several work activities. In analyzing these data we have multiplied proportion of time spent in a specified activity by the number of psychologists reporting that proportion, summing these products for each activity. Our analysis provides estimates of the manpower effort in each activity stated in terms of an equivalent number of individuals engaged 100% of their time in that activity. Remarkably, our equivalent-effort figures are virtually identical with recent National Register proportions.

- Ninety-four percent of the membership is white, according to these data, and the same proportion obtains for the total sample. Only 287 members indicated that they were black, a figure which if extrapolated to the total membership would yield about 370 black members as of 1972. This question was left blank by almost a third of the respondents.

- Association members and North American psychologists in general are primarily citizens of the United States, 97% of both the membership and total respondents so indicating.

A Backward Look before Moving On

During the 20 years that have now elapsed since 1954, the year of the first NRSTP, a number of major world events have had significant effects on psychological and other scientific manpower (among other things, to be sure). In 1957, in the midst of the continuing Cold War hysteria, Russia, by launching the first known orbital satellite, Sputnik, demonstrated to the American public a significant technological sophistication and extensive manufacturing capability in the area of rockets and missiles. Not since Pearl Harbor (even including Korea) had the threat of foreign power mobilized the American spirit into such unity of purpose that the goal of putting a man on the moon in 10 years was accepted as a popular mandate. Cost was no object. Federal funds poured into the general scientific enterprise at all levels—from educating the public; to training scientists; to greatly expanding the scientific research capability of the universities and institutes; to research, development, and production activities. Concomitantly, the post World War II “baby boom” exploded upon the colleges and universities, and the ensuing demand for a college education led to a major expansion in university physical plant and faculty. The enrollments in colleges almost doubled from 3,039,000 in 1960 to 5,956,000 in 1970 (U.S. Dept. of Commerce, 1973, p. 131).

Ten years ago Allan Cartter (1965) predicted that such rapid growth was a sometime thing, that a leveling off of the growth of the college-age cohort would inevitably curb higher education expansion and stabilize university and faculty size. Such a prognostication was borne out by 1970 in most disciplines, the exceptions being the social sciences, medicine, and law. The slowdown was exacerbated by an economic recession affecting the aerospace

and related industries and notably the fields of engineering and the physical sciences when the achievement of reaching the moon had been put into perspective.

Other events of the late sixties—the disenchantment with the Vietnam war and a growing concern for mankind's predicament—seem to have led students out of the sciences and humanities and into fields seen as "socially relevant."

Psychology's growth partook deeply of this whole vast development. Funds were readily available for psychological training, for research, and for physical plant expansion in the universities. Training capabilities were vastly increased. Only 665 doctorates in psychology were awarded in 1954 (NAS-NRC, 1963). In 1974 this figure will be about 2,600 (USDHEW, 1973, p. 58). In 1954, graduate enrollment in psychology was about 3,600 (Moore, 1955); in 1972, the figure was 38,000 (Cuca, 1974). Undergraduate baccalaureates in psychology have soared to 100,000 per year. Because of this growth, the educational system has placed great demands on the supply; half of all psychologists, as we have seen above, were employed in institutions of higher education according to our 1972 survey.

Between 1954 and 1974, the growth of the Association has soared from 12,380 to 37,371 members. The number of psychologists responding to the 1954 National Register questionnaire was 10,163. Our total 1972 questionnaire return numbered 35,361. One can be struck by other impacts of the events of the 18 years between 1954 and 1972. In Table 2 we have abstracted by six-year intervals a sample of interesting trends that give some of the fine-grain detail of psychology's growth. These data are taken from NSF publications⁶ for the years 1954, 1960, and 1966. The APA data are used for 1972.

The figures showing growth are among the most striking, of course, including the growth in median salary,⁷ but signs of stability are noteworthy in their own way. In comparison with other sciences, psychology's growth is typical, not unusual. Psy-

TABLE 2

Some Interesting Trends in the Growth of Psychology since 1954

	1954	1960	1966	1972
No. psychologists in APA	12,380	18,215	24,473	33,629
No. psychologists reporting	10,163	15,257	19,027	37,361
Proportion of psychologists employed in:				
Clinical psychology	.34	.39	.36	.36
Human service subfields	.51	.56	.53	.56
Educational institutions	.51	.46	.51	.62
Industry-business/self-employed	.11	.16	.14	.15
Proportion of psychologists with doctorates	.56	.59	.66	.69
Proportion of male psychologists	.78	.78	.78	.76
Median salary of male psychologists				
Total	5,900	8,000	11,500	19,500
Doctorate	6,600	9,000	12,100	20,000
Masters	5,000	7,000	9,800	17,000
% of total doctoral scientists	12.4	14.5	13.9	10.9
% of total scientific manpower pool	8.8	7.6	7.8	NA

Note. Data for 1954, 1960, and 1966 are taken from National Science Foundation publications. APA data are used for 1972. NA = not available.

chologists comprised 8.8% of the scientific manpower pool in 1954 and 8.4% in 1970, the last year for which NSF comparison figures are available. Psychologists' median salary was 90.4% that of the total in 1954; 100% (or equality) in 1970. In terms of doctorates only, psychology's share decreased from 12.4% (NSF, 1959) to 10.9% (NAS, 1974) of the total pool in science fields in 1973.

A few additional comments about the data displayed in Table 2 are worth noting. Undoubtedly, the influence of government training subventions underlies the gradual increase in the percentage of doctorates from 56% in 1954 to 69% in 1972. Perhaps the early Veterans Administration and National Institute of Mental Health programs funding clinical psychology training account for the rise between 1954 and 1960 in the percentages of individuals in clinical (from 34% to 39%) and in the human service subfields (from 51% to 56%). After 1960, the availability of other government training funds must have attenuated that relative growth and expanded all fields of psychology relatively uniformly.

The effect of the rapid expansion of the schools and colleges is reflected in the changes of psycholo-

⁶ Data from the periodic canvases of scientific fields of the National Register are presented in extensive form in NSF biyearly publications entitled *American Science Manpower* for the years 1954 through 1970.

⁷ In terms of constant dollars, the 1954 median of \$6,600 is equivalent to \$12,000 in 1972 dollars as determined using the implicit price deflators of the Bureau of Economic Analysis (U.S. Department of Commerce, 1973).

^a N is the number of full-time-equivalent psychologists.

^b The number of years since highest degree awarded.

gists employed in educational institutions. From 1954 to 1960, this figure actually decreased from 51% to 46%, possibly because of the relative increase of service-oriented clinical psychologists. By 1972, however, the percentage of psychologists employed in educational institutions had increased to 62%, of whom the bulk, 50% of all psychologists, were employed in institutions of higher education.

One further aspect of the data in Table 2 merits comment. The relative increase of those employed in private industry or self-employed between 1954 and 1960 is probably due to two factors: (a) increase in the relative percentage of clinical psychologists and (b) the potential for private practice brought about by statutory recognition of psychologists for such practice, a significant development of that time for psychology.

A Closer Look at APA Psychologists

Having spent some time reviewing results from the APA Manpower Data System that provide a sequel to the NSF National Register, let us now focus on APA membership. As we have mentioned, it is likely that future detailed statistical information will be available only on Association members. Thus, a baseline of current member characteristics is needed against which future state-of-the-field comparisons can be made.

Level of education must be an integral part of any membership analysis because membership categories are defined by academic degree. Gender is an additional factor of importance for the analysis due to current concerns over the extent to which women are represented in the psychological community and because of their relative representation within the fine structure we have been observing. In order to provide data illuminating these several aspects of the membership, we have chosen to present a breakdown of the membership data by degree level and by sex but otherwise in essentially the same format as was employed earlier in considering the total responding sample.

Table 3 contains membership characteristics data for doctorate and master's-level individuals and for men and women separately in each of these educational levels. Because of the small number of bachelor members, we have not considered them in these fine-focus analyses. The numbers reported in each column are the numbers of members of the particular subgroup responding for the specific characteristic.⁸ The percentages for each characteristic are based upon the number responding.

⁸ The total membership information is given by characteristic in Table 1. In most instances, the subtotals in Table 3 will not sum to the corresponding totals in Table 1 because some respondents chose not to provide gender information.

With these considerations in mind, then, we can proceed to examine in more detail the APA membership characteristics. We shall attempt no exhaustive analysis of the data. They are presented for the information of the reader whose own interests will provide more specific questions which hopefully the data illuminate.

There are, however, some interesting differences to point up among categories of members. For example, it seems clear that a much higher percentage of master's-level members are in the applied subfields—engineering through school psychology—than are doctoral members (90% versus 61%). Moreover, it seems that doctorate men resemble doctorate women in their choice of subfields with the exception of developmental and industrial/organizational where major differences exist. Similarly, the men and women masters are alike except for a relative preponderance of master's men in industrial/organizational psychology and master's women in school psychology.

Looking at employment setting, one must again be impressed with the percentage of members who are employed in educational settings. The moderator, educational level, however, has a strong influence as doctoral men and women are employed predominantly in colleges, whereas the master's-level men and women, and particularly the women, are employed in precollege settings.

Employment in a school setting is also reflected in the employment auspices, with local government being the primary employer of master's degree holders, while for the doctoral individuals the state government and independent nonprofit institutions, both major university support categories, are significant employers.

The large influx of younger psychologists into the total manpower pool and into the ranks of the members of the Association is clearly seen in the virtually monotonic increments of all categories of the years of experience section. In 1972, 60% of the doctorates and 50% of the masters in the membership had received their highest degree within the last 10 years. Moreover, it would appear that the proportion of younger women doctorates is increasing faster than that of the men, with some 65% of the women doctorates having 10 or fewer years since receiving their highest degree.

In terms of age, psychology seems a young profession, with 43% of both doctorates and masters being less than 40 years old in 1972.

Finally, with respect to racial/ethnic identity, there emerges a picture similar to that seen earlier for our total group of psychologists. The percentage of black members with the master's degree is slightly higher than the percentage with the doctorate, although the percentages at both educational levels are still, unfortunately, trivial relative to the total psychology manpower.

Employment of Psychologists

As indicated in the introduction to this article, the employment status of professionals, particularly scientists, engineers, and academics, is a matter of continuing policy concern. As further noted, the continued firmness of the market for psychologists has been encouraging. One is tempted to add that the demand seems not linked straightforwardly to salary levels. Psychologists have not yet priced themselves out of the market. They may not even have gotten their fair share! Following up on such speculation is not the subject of this article, however.

What emerges from the manpower data is an encouraging picture for psychology in 1972. The pertinent data are presented in Table 4. Of a total of 33,575 member and nonmember respondents, 2,811 or 8.3% reported that they were not employed at the time of filling out the questionnaire. The bulk of these were students (1,686); and only 682 or 2% of the total were actually seeking employment. Since many of those seeking were undoubtedly students, the ranks of the unemployed in psychology were very small. On the other hand, 11.3% of those already employed were seeking other employment. Much of this can be seen as the inevitable consequence of a university up-or-out system, but some may represent mismatching, perceived underemployment, or simply dislike for one's present employment. The operant level for that variable is unknown!

Also indicating demand is the substantial number of psychologists who are engaged in employment other than a full-time job. Of the total, for example, 28% have a part-time position in addition to full-time employment. Another 8% piece together a career out of one or more part-time positions. As reported elsewhere (Boneau, 1974), it is preponderantly men who have a part-time job in addition to full-time employment, while it is women who are predominantly engaged in part-time-only careers. One is tempted to conjecture that the

TABLE 4

Employment Status of Psychologists

Seeking employment	79	75	49	69	280	402	682

level of remuneration of psychology's professional salaries may not be sufficient to support aspirations, hence the moonlighting. The data are not available to test such a hypothesis, nor is there information from other fields.

The Salaries of Psychologists

About 21,000 member respondents (77% of the respondents) provided the salary information solicited on the questionnaire.⁹

In Table 5 we have chosen to present the median, the first and third quartiles, and the first and ninth deciles in those subcategories in which 20 or more respondents provided salary information. For categories having between 10 and 20 respondents, we have given the median only, and for subcategories containing fewer than 5 respondents we have presented no data. The *N*s upon which distributions are based are not presented.

A few further comments are called for. Controlling for years of experience (data not presented here) makes inconsequential the difference between member and nonmember data. It may be assumed that member data are representative of psycholo-

gists in general, at least for the purpose of presenting salary information.

The data of Table 5 are from those individuals who indicated full-time employment (see Table 4) and are based only upon the financial remuneration from that full-time employment excluding fringe benefits. Academic salaries on a nine-month base were normalized by adding two ninths of salary prior to obtaining the distribution. Those self-employed full time are also included. Presumably, their "salary" represents net of income less business expenses.

The data of Table 5 are presented essentially without comment. We cannot avoid, however, remarking on the general similarity between the salaries of doctorate women and those of master's men, not doctorate men. A look at this comparison a few years hence should prove of interest.

An additional comment is prompted by the stated rationale of the federal government to phase out funds for graduate training on the grounds that it is inequitable to provide free training for those who will have a high income potential because of that training (Edwards, 1973). One might argue that with average hourly wages for journeymen electricians and plumbers now in the \$8-\$11 per hour range depending upon location (Bureau of National Affairs, 1974), figures which put them around the median for our doctoral salaries, it seems difficult to understand that psychologists have

⁹ Since salary depends significantly upon the degree level and the sex of the respondent (as well as upon other factors, of course), we have provided salary information for members in essentially the same format as Table 3.

Note. In thousands. D₁ = 1st decile, Q₁ = 1st quartile, Q₃ = 3rd quartile, D₉ = 9th decile. Ns are the number in a cell, not the number on which the salaries are based.

attained the "high income" warranted by their education.

Such a generalization is hazardous, even if tempting. A glance at the years of experience section tempers the generalization by showing median salaries in the \$27,000 range for doctorate men after 20 years of experience. The preponderance of young psychologists with fewer years of experience keeps the median salary low. One, of course, might argue that \$27,000 after 20 years is not necessarily a demonstration of a "high earning potential," particularly with entrants to the field earning \$15,000. The \$27,000, however, is perhaps five times the 1952 entrance salary (albeit not in constant dollars) of those entering the field at that time. For what it is worth, the same reasoning implies that those now in graduate school would seem to have a high probability with a doctorate of earning better than \$75,00 per year by 2000. We wonder what it will buy!

In Table 6 is presented one of a virtually inexhaustible combination of variables. Because subfield and work setting constitute a sociologically significant combination of occupational variables, however, it seems important and interesting enough to warrant presentation. Table 6 provides an enumeration of the number of individuals in selected subfield/work-setting combinations. To keep the size of the table within reasonable bounds, we have presented only those particular combinations having a sizable *N*.

A demographic variable of interest is geographic location. In Table 7 we have presented the numbers of psychologists having business addresses in the states and other geographical locations listed. Also provided is an abbreviated salary distribution by state containing the median salary and first and ninth deciles. These data are presented without comment except to note that some 27% of the membership is located in the two states of New York and California, states that comprised about 19% of the total population of the United States in 1972.

Salary is not the only source of professional income for psychologists. Consulting, royalties, part-time teaching positions, part-time fee-for-service activities, all serve to supplement the income of those employed full time. Referring back to Table 4, we see that nearly one third of those fully employed also have a part-time position. Because the questionnaire solicited information about total pro-

fessional income, we can calculate the incremental income from these sources for those who report it.

In general, the results (not tabulated here) are reasonably uniform across characteristics, with a median of about \$4,000 for male doctorates with five or more years of experience who have extra income and report it. There is a time cost for extra income, of course. Like many professionals, psychologists spend considerably more than 40 hours per week in their professional activities, as data from the survey reveal, a median of 46.6 hours per week for doctorate males (Boneau, 1973).

Is the APA Representative of Psychology in General?

The American Psychological Association is the largest society of psychologists in the United States. It is a major voice for the concerns of psychologists and a major vehicle for representing psychology to the public and to the makers of public policy. For this reason it is important to have some idea of the degree to which the various identifiable segments of psychology have access to and influence on the APA governance. Does the APA, in fact, speak for all psychology, or are some segments represented disproportionately or not at all?

This question, as phrased, is the result of rumination by an APA insider. A related question—perhaps the same question—couched in terms meaningful to an outsider asks for the *total* number of psychologists, APA members as well as nonmembers, and for the number of psychologists of various kinds. A description of the APA membership is an insufficient answer to those questions, but how insufficient? Clearly the 1972 APA Manpower Data base precludes definitive statements even of APA membership since only 77% of the members returned questionnaires. On the other hand, we have argued that the 77% sample is trivially different from the 1972 member population (see footnote 3).

Let us consider the doctorate holders first. Assuming a relatively unbiased sample, we can extrapolate our 77% return to the total membership and estimate the total doctorate population to be about 27,700. The additional 2,900 nonmember doctorates in the file yield a total of 30,600 doctorates in psychology in 1972. The National Academy of Sciences (1974) on a sampling basis has concluded the number of doctoral psychologists in 1972

Note. In thousands. D₁ = 1st decile, Q₁ = 1st quartile, Q₃ = 3rd quartile, D₅ = 9th decile. Deciles, quartiles, and medians are not given for Ns less than 10. Only medians are given for Ns greater than or equal to 10 and less than 20.

to be between 24,000 and 27,000 depending upon the definition.¹⁰

The NSF, for its own purposes, from NAS data leans to a total of 28,286 doctorate holders who either possess a PhD in psychology or who are now working in psychology. In general, the NAS and NSF definitions ignore psychologists who received a degree in education. These include educational, counseling, and school psychologists, perhaps others, who are eligible for membership and identify themselves with psychology, whether or not they join the Association. The number of these individuals is unknown and is inextricably entwined in the statistical summaries of all extant data systems including that of APA.¹¹ A reasonable guess is that the number of education-trained psychologists is in the neighborhood of 4,000, of whom an unknown fraction but probably about 75% are already in our files. Committing *petit legerdemain*¹² with these figures yields an estimate in the range of 31,000–32,000 as the total population of doctorate psychologists APA-style in 1972, and a conclusion that about 90% are members of the APA.¹³ Ignored in such manipulation are such factors as the knowledge that 10% of the doctorate psychologists are employed in another field and that some 10% of those employed in psychology have a doctorate in another field (NAS, 1974). Hopefully, such complications are either built into the gross estimates or cancel themselves out.

A slightly different approach yields essentially the same gross conclusion but provides a needed fine-grain discrimination among subfields. The data come from the NAS Doctorate Record file compiled from a yearly survey of new doctorate recipients in all fields. Published data include subfields within fields and permit us to compare the actual number of recipients in various subfields with the numbers

of respondents who received a doctorate in those subfields. Such a comparison in selected subfields reveals that about 87% of the doctorates are APA members.¹⁴ According to these data virtually 100% of the clinical psychologists are members but only, perhaps, 75% of the experimental psychologists. We may conclude on the basis of the two arguments that APA membership includes about 90% of the eligible doctorate holders.

As for master's-level members, the data are much harder to find. Our extrapolated total of 7,300 in the membership is a percentage of some unknown base. According to figures from the Office of Education (HEW, 1972) and the American Council on Education (1970), approximately 60,000 master's degrees were awarded in psychology between 1932 and 1972. According to our estimates, some 24,000 of these were awarded the PhD at some later date, leaving 36,000 having the master's as their highest degree. Assuming 6,000 have died and one third have left the field, we arrive at a figure of some 20,000 masters. Of our 7,500 master's holders, perhaps 5,000 received their MA in psychology departments, the remainder elsewhere. Thus, our 5,000 psychology masters provide the basis for a guesstimate that approximately one fourth of those eligible are members. The remaining master's-level members are predominantly school and counseling psychologists, whose number are unknown but must be in the neighborhood of 30,000–40,000 depending upon how they are defined.

In short, we may conclude that the APA contains a preponderance of the doctorate psychologists in the country and may be considered to represent them. The Association, however, would seem not to represent master's-level psychologists and, in particular, those from the educational subfields.

American Council on Education. *A fact book on higher education*. 4th ed. Washington, D.C.: Author, 1970.

¹⁰ The NAS counts doctorate degree in a field, identification with a field, or employment in a field as separate defining characteristics. By these definitions, the 1972 NAS sample produces estimates of 24,483, 26,655, and 24,598, respectively (NAS, 1974).

¹¹ Fortunately, Mark II of the APA system will permit a differentiation between EdDs and PhDs, thus shedding light upon the collegial origins of psychologists.

¹² A technical procedure apparently utilized by most, if not all, manpower experts, at least in Washington, D.C. This exercise may serve to enlighten those who wonder where the numbers come from.

¹³ By 1974 the number of doctorate psychologists has increased by some 5,000. There are now some 37,000 doctorate psychologists. The prospect seems to be for an even more rapid increase in the next few years (Cuca, 1974).

¹⁴ Data were compared for the subfields experimental-comparative-physiological, personality-social, and clinical to concentrate on those areas in which NAS and APA might be expected to have the same individuals. Over a 20-year period from 1952 to 1972, the number of doctorate recipients in these subfields was 12,979. The total extrapolated 1972 APA membership in these subfields was about 11,300 or 87%. The basic reference is NAS (1967). NAS updates the figures yearly in a pamphlet entitled "Summary Report."

Proposed Bylaws Amendment

At the meeting of August 31 and September 2, 1974, the Council of Representatives, on recommendation of the Board of Directors, approved submission of the following Bylaws amendment to the APA membership for approval:

Amendment to Article I of the APA Bylaws to add the words "and profession" after the word "science."

Article I—Objects¹

The objects of the American Psychological Association shall be to advance psychology as a science and profession

and as a means of promoting human welfare by the encouragement of psychology in all its branches in the broadest and most liberal manner; by the promotion of research in psychology and the improvement of research methods and conditions; by the improvement of the qualifications and usefulness of psychologists through high standards of education and achievement; by the establishment and maintenance of the highest standards of professional ethics and conduct of the members of the Association; by the increase and diffusion of psychological knowledge through meetings, professional contacts, reports, papers, discussions, and publications; thereby to advance scientific interests and inquiry, and the application of research findings to the promotion of the public welfare.

¹ Italicized material is added.

APA-Approved Internships for Doctoral Training in Clinical and Counseling Psychology: 1974

AMERICAN PSYCHOLOGICAL ASSOCIATION

The Committee on Accreditation has approved for doctoral training in professional psychology the internships offered by the agencies listed below. The criteria for evaluating these programs can be obtained from the Educational Affairs Office.

The current criteria for accreditation of internship training programs no longer make the distinction between clinical and counseling internship programs; therefore, the separate listing of approved programs by professional specialty has been dropped. Readers desiring information on training goals offered at specific agencies are encouraged to write directly to the agencies.

Each of the agencies listed has met the same qualitative standards with respect to adequacy of training. The list is alphabetical by agencies.

Fully Approved Programs

- University of Alabama Medical Center, Box 314, University Station, Birmingham, Alabama 35294.
- Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, New York 10461.
- American University Counseling Center, Mary Graydon Center, Nebraska and Massachusetts Avenues, N.W., Washington, D.C. 20016.
- Area A Community Mental Health Center, 3246 P Street, N.W., Washington, D.C. 20007.

Scientific Awards Announcement

The Committee on Scientific Awards is accepting nominations for its award program. The Committee selects up to three persons as recipients of the Distinguished Scientific Contribution Award who, in its opinion, have made the most distinguished theoretical or empirical contributions to scientific psychology in recent years.

A new award, the Distinguished Contribution for Applications in Psychology, has been authorized by the Board of Directors and will be given for the third time this year. This is presented to an individual who, in the Committee's opinion, has engaged in a program of research which is systematic and applied in character.

The awards are subject to the following limitations: (a) members of the Committee, former recipients of the awards, the President and the President-elect of the APA shall be ineligible. (b) The Committee shall seek diversity in selecting recipients, avoiding as far as possible the selection of more than one person representing a specialized topic, a specific material, a given method, or a particular application.

Names and appropriate information which will guide the Committee on Scientific Awards in conducting an intensive career review and evaluation should be forwarded to Office of Scientific Affairs, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036. *Deadline for nominations is January 15, 1975.*

APA-Approved Doctoral Programs in Clinical, Counseling, and School Psychology: 1974

AMERICAN PSYCHOLOGICAL ASSOCIATION

The Committee on Accreditation has approved the doctoral training programs in clinical, counseling, and school psychology that are conducted by the institutions listed below. In the institutions listed, the approved programs are directed by the department of psychology unless otherwise indicated. Programs that have not requested evaluation, and programs that have been evaluated but not approved, are not included in the list. The criteria for evaluating these programs can be obtained from the Educational Affairs Office.

The Committee on Accreditation has dropped the "initial" category of accreditation. Therefore, programs that meet all of the criteria, including newly approved programs, are classified as fully approved.

Inclusion of an institution in this list indicates approval of doctoral programs in clinical, counseling, and school psychology only. Inclusion or noninclusion carries no implications for other graduate programs in psychology or for programs of graduate education in other disciplines.

The institutions listed below have been reported to the United States Public Health Service, to the Veterans Administration, and to the Surgeon General's Office, Department of the Army, as conducting at the present time approved programs of doctoral training in the areas indicated.

A Courageous Man

Beit-Hallahmi (February 1974) is a courageous man. Psychologists who take on the prevailing theories about intelligence and its distribution face the wrath of leaders in one large sector of our science. To confront as well the swelling ranks of clinical, counseling, and community psychology is tantamount to setting up a lonely high noon encounter.

No wonder Beit-Hallahmi concluded his article with a poignant note about the role of the critic. Standing against the mainstream in one's own field is alienating, as Darwin revealed about himself (Gruber, 1973). By the time he sufficiently overcame his anxiety to be able to reveal his theories, Darwin at least had the necessary evidence to document them. In a science like psychology, however, which is both ahistorical and dominated by the canons of the British empiricist traditions, logical inferences about changes in human behavior, formulated under conditions different from those of today, carry no weight whatsoever.

The hard-nosed psychologist values here-and-now data. Predictions made by American and British psychologists in the 1920s and 1930s based on theories of intelligence and contemporary test results proved to be grossly inaccurate.

Those historical facts are either forgotten or ignored today as other psychologists using the same theories and current test data make similar highly publicized statements, again with serious consequences for the well-being of people.

Let no psychologist be deluded into believing that these here-and-now comparative data do not leave their imprint on the minds of teachers, parents, and children, as well as psychologists. The pity of it is that psychology permits only defensive

measures in counteracting the use of contemporary data; one must go to other disciplines for more powerful intellectual weapons. It is regrettable but true that the nature of psychology makes it more amenable to sustain than to alter the social-political status quo; it is not simply to agree with Kuhn (1970) that psychologists work within the limits of the prevailing "paradigm." Beyond that, the possibilities of generating radically different paradigms from within psychology are remote.

In Response to "Up with Our Foremothers"

I enjoyed the article by Bernstein and Russo (February 1974). I generally agree with the purpose of the article and believe the situation described needs correction. However, as indicated by the following quotation, the article included a reflection upon our profession which may or may not be warranted:

We will probably never know how much work was done by women but credited to men: how many footnotes of appreciation should rightfully have been coauthorship, how many times junior authorship should have been senior authorship, or how many times it was the

male coauthor who should have received the footnote [p. 131].

It seems to me that this statement should be made only if there is a record of cases of the type described. As one of the women listed in an opening question in the article, I might indicate that my own experience has been quite the opposite of the practices suggested in the quotation. I was, in actuality, my husband's student before and for some years after I took my degree. I also worked as his assistant and statistical consultant for some six or seven years, and enjoyed being associated with his interesting research and theoretical system. During that time he made a practice of including my name on publications which did not call for that type of recognition.

My own thing later became the development of a career in clinical psychology, which suits my own interests. I prefer a separate career and recommend this type of arrangement. However, I learned a great deal in those early years which I now value very much. I have thus described my experiences for the record to point out that not all man-woman relationships are of the type Bernstein and Russo described. We should not conclude that our profession can generally or even occasionally be characterized in this manner without some evidence.

The Arrival of Women's Lib

In her discussion of studies of achievement motivation in college women, Alper (March 1974) skirted a much more general phenomenon than the inconsistent findings of her research. The generality was that social-psychological-motivational theories of "all" sorts can be applied better to men than to women.

A speculative explanation of this sex difference is that, by and large, theories are spun by men, the implications of the theories are derived by men, and the experimental tests are designed by men. If the theories were tight, if the derivations of hypotheses were strictly logical, and if the operationalization of definitions for experimental tests involved necessary criteria (or if men understood women), the differences would disappear. The notion that achievement motivation in a society produces technological progress is, indeed, more notion than theory. That making good grades indexes achievement more than, or rather than, docility is a hunch—reasonable, but arguable. When the theorizing and experimentation are done by men or by women whose selection and training were dominated by men, tests are masculinized to a point that more often than not misses the .05 level of confidence when applied to women.

A second speculation is that when these differences no longer plague the psychological literature, women's lib will have arrived.

PAUL B. PORTER
University of Utah

On "Learning Theory"

Freedman, Cohen, and Hennessy (March 1974) essentially stated the general idea that people act rationally as they (the people) see it, even in laboratory-type learning experiments. They reported some difficulties in devising an experiment that would support the contention but eventually did so by presenting a display to which the subjects could apply their past experience intelligently. They concluded that the behavior of people in the laboratory depends upon the expectancies people bring into the laboratory as well as what happens to them thereafter.

Gladstone anticipated the report and went beyond it in several ways. Gladstone used a standard Skinnerian operant conditioning and extinction design except that the rewards were open to observation and, therefore, the subjects could see when they had obtained the last reward. Under those conditions: (a) fewer college students yielded extinction responses and the group as a whole yielded fewer extinction responses than the group that could not see the rewards (Gladstone, 1966b); (b) most college students yielded extinction responses even when they could observe the exhaustion of the rewards (Gladstone, 1966b); (c) the number of students yielding extinction responses in the reward-visible situation was cut down a great deal when punishment was added for each response (Gladstone, 1966a; Gladstone & Miller, 1968); (d) almost no subjects yielded extinction responses when they were forced to pay attention to the visible rewards in addition to being punished for responding (Gladstone, 1968); (e) older chil-

dren are more prone than college students to stop abruptly when the rewards are gone (Gladstone, 1966a, 1969); (f) young children are more likely than older children to yield extinction responses (Gladstone, 1966a, 1969); and (g) almost all young children act completely rationally (yield no extinction responses) when the rewards are visible and the situation they are asked to deal with is very simple (Gladstone, manuscript in preparation).

I am happy to see the idea make the big time.

The Observer's Temporal Scope

Freedman, Cohen, and Hennessy (March 1974) hypothesized that "initially, in the learning situation, when an organism makes a response and that response is followed by reinforcement, there is an increase in the probability that the response will not be repeated under the same stimulus conditions [p. 204]." Moreover, it is their contention that if the

above hypothesis is confirmed, its confirmation narrows the boundaries under which the most basic law of learning theory, the law of effect, holds. Their argument seems to be based on the assumption that in accordance with the law of effect, when an organism makes a response and that response is followed by reinforcement, there is an increase in the probability that that particular response will be repeated under the same stimulus conditions. Clearly, then, a critical and central issue emerges: How does one identify the reinforced response? An attempt will be made in this reply to shed some light on this issue.

The fact that when given two alternatives from which to choose there is a tendency among human and non-human organisms to select on the second opportunity the opposite alternative from that chosen on the first opportunity, even if the first was reinforced, can be interpreted in at least two ways. An initial interpretation, favored by Freedman and his associates, is that under these particular circumstances the law of effect is inoperative because a response followed by reinforcement did not increase in its probability of occurrence under the same stimulus conditions. Another, more parsimonious interpretation becomes available when the observer's temporal scope is expanded. To begin with, one may examine the potential impact of an observer's temporal scope under circumstances that are different from the study of Freedman et al.

An observer may look at a pigeon that is continuously pecking a green light until the pigeon collapses from exhaustion. He may also note that each peck is not followed by any conceivable reinforcement. This observer may then tentatively conclude that a basic law of learning does not hold in this particular situation because a response that is not reinforced should not increase in its probability of occurrence under the same stimulus configuration. And yet this is precisely what he is wit-

nessing. Or is it? What is the response? And what is being reinforced?

If the observer extends his temporal scope he may note that before he entered the laboratory the pigeon was intermittently reinforced for a successively larger number of pecks. If a long series of pecks, indeed only a long and continuously expanding series of pecks, were previously reinforced, then the law of effect is clearly not violated (Ferster & Skinner, 1957). The response that was followed by reinforcement did increase in its probability of occurrence under the same stimulus conditions.

Let us return to the study of Freedman, Cohen, and Hennessy. Freedman et al.'s interpretation of the confirmation of their hypothesis is derived from a particular temporal scope. They observe a subject who is choosing between two boxes. Underneath one box there is a quarter. Luckily the subject chooses this particular box. Nevertheless, on the next occasion, they observe that he selects the other, previously unreinforced box. At this particular point, they claim that the law of effect is clearly inoperative.

Now, had the same investigators expanded their temporal scope, had they conducted a longitudinal study with the same subject, their view of what the reinforced response is might have changed. They might have observed that in his daily life the subject has learned that the supply of reinforcers from a specific source is, at times, finite. Accordingly, this subject understands that he may ultimately receive the greatest number of reinforcers when he adopts a behavioral strategy that will assure exposure to as many potential sources of reinforcement as possible. The probability that a strategy will be maintained increases when it proves to be a reinforcing strategy. Any instance in which a particular strategy is maintained because it is followed by reinforcement, albeit intermittently, is clearly a good ex-

ample of the applicability of the law of effect.

The organism's assumptions to the effect that (a) once a reward is consumed or removed, given no other information, it may no longer be present on the next exposure; and (b) other organisms may be deceptive, could have emerged, and in all probability did emerge, because they were intermittently reinforced. Consequently, when an individual who was reinforced for one response then chooses not to repeat that response, one potential inference is that this behavior or response constitutes a part of a strategy that has been previously reinforced.

A response, viewed in isolation, apart from the role that it plays in a strategy, may be meaningless. Its definition must take into account this response's role, if any, in a more global strategy. Given that a response is an integral part of a particular strategy, then the relevant reinforcement should be viewed with respect to that particular strategy and not in relation to that specific response.

Viewing human and nonhuman behavior from a broad, evolutionary perspective, an observer may note that a flexible strategy, rather than a specific, highly predictable, and rigid response, may lead to more reinforcements. This flexible strategy may involve the continuous shifting and alternating of behavior. This continuous shift may be reinforced by the fact that the organism's opponents and/or predators may become confused because their target's impending behavior will remain in doubt, camouflaged by uncertainty.

Organization of Central Office

It was very informative to read in the June issue about the Central Office organization of the APA (Little, 1974). Most interesting of all was finding out who the people are who head the different offices, departments, and divisions.

I was most surprised to discover that of the 23 persons identified as heading a unit, only 4 are women and none occupies a position higher than head of department. This figure is only 16% of all positions identified (two males occupy two positions

each). If the minority representation for graded staff has been increased from 15% in 1970 to 23% in 1973, why is there not an equivalent representation on the executive side?

Is the distribution of women in the governing body of the Central Office representative of the practices proposed in the Affirmative Action plan that was prepared in 1973? Is this the reason why the praise from the Board of Social and Ethical Responsibility for Psychology was not wholehearted but qualified with "faint damns"?

I hope that the first function of the Committee on Women in Psychology, following its stated purpose according to Rule of Council 60-13.1, will be to make strong recommendations to the Central Office regarding the composition of its governing body.

NOTICE TO APA AUTHORS

The American Psychological Association announces publication of the second edition of the *Publication Manual* in August 1974. This new edition, which supersedes the 1967 Manual, will be adopted by the 14 APA journals in 1975.

The new Manual is more comprehensive than the previous edition. It updates APA publication policies and procedures and incorporates changes in editorial practice since 1967. For instance, APA now sends many authors their copy-edited manuscripts for review before they are set into type, and some editors now use blind review procedures. The second edition also includes up-to-date statements of the coverage of each APA journal including the *Journal of Experimental Psychology* which will be published in four separate sections in 1975.

The new *Publication Manual* initiates several changes in APA style. These changes are announced in the August 1974 *American Psychologist* and will be introduced in the APA journals in January 1975. During the period of transition to the new style, authors should note that (a) all manuscripts published in 1974 will be copy-edited according to the 1967 Manual, (b) manuscripts accepted in 1974 and published in 1975 will be copy-edited to conform to the new Manual. Starting in 1975, accepted manuscripts that depart significantly from the Manual will be returned to authors for correction.

Authors will be encouraged by the changes in the second edition. The new APA style simplifies reference forms; eliminates unnecessary underlines, brackets, and other devices; supports appropriate use of "I" and "we"; and generally clarifies typing requirements. Material is arranged for maximum convenience to authors and typists, and all sections are cross-referenced and indexed.

The new *Publication Manual* is available after August 1 for \$3. Send orders to APA Publication Sales, 1200 Seventeenth Street, N.W., Washington, D. C. 20036. Orders of \$15 or less must include payment unless they are submitted on institutional purchase order forms.

Psychology in Action

USEFULNESS OF IN-SERVICE TRAINING WORKSHOPS FOR COUNSELORS

STEPHEN I. ABRAMOWITZ	<i>Vanderbilt University</i>
LAWRENCE J. WEITZ	<i>George Peabody College for Teachers</i>
CHRISTINE V. ABRAMOWITZ	<i>George Peabody College for Teachers</i>
HOWARD BERTHOLD	<i>Union College</i>
FRANK M. CALABRIA	<i>Union College</i>
MIRIAM CONABLE	<i>Union College</i>
ROBERT GIBLIN	<i>State University of New York at Albany</i>
FRED F. SELFRIDGE	<i>Valley Central Middle School¹</i>

The desirability of continuing education and training for school counselors is well recognized (Ohlsen, 1969). According to the Commission on Guidance in American Schools (Wrenn, 1962), the school counselor should "consider professional updating a continuous process . . . and . . . attempt to understand himself better through counseling or other professional help [pp. 180-181]." The recurrent upheavals within the youth culture in the ensuing decade underscore the relevance of the Commission's charge.

Consistent with this view, O'Hara (1968) pointed out the responsibility of counseling educators to cooperate with school officials in providing postgraduate on-the-job monitoring of former students: "That counseling educators should know what their graduates are doing and provide them with opportunities for further professional growth is obvious [p. 213]." Gust (1969) believes that on-site supervision of the counselor's care-giving activities could ultimately bolster the profession's public image by enhancing the quality of services delivered.

However, in-service supervision or training is more frequently preached than practiced and rarely evaluated when it has been implemented. Controlled experimental investigations of its impact are essentially nonexistent, which is unfortunate from an applied as well as a scientific perspective. Financially beleaguered administrators can hardly be faulted for being reluctant to subsidize a new spending adventure whose effective-

ness is substantiated only by polemic exhortation and anecdotal report. Legislators attuned to the pulse of a public disenchanted with university-connected innovation also are unlikely to be enthusiastic, especially when greater emphasis is being accorded experientially oriented and other novel teaching modalities (Association for Counselor Education and Supervision, 1964; Hill, 1968). Despite the fact that their popularity in some circles outpaces their scientific credibility (Lieberman, Yalom, & Miles, 1973), sensitivity, encounter, and other formerly avant-garde techniques of relationship-skill acquisition and personal growth now regularly complement more conventional, didactic instruction.

Developing Maslow's (1954) writings on the fully functioning person, Rogers (1961) championed the notion that a care-giver's personal qualities are at least as important as his accumulated conceptual and technical skills in determining counseling effectiveness. Others within the client-centered tradition have recently advanced a more extreme position, asserting that a counselor's professional success cannot transcend the quality of his everyday life (Carkhuff & Berenson, 1967). Polemics aside, do more self-actualized persons in the client-centered sense make better counselors? The meager evidence tends to be affirmative. Combs and Soper (1963) found that supervisor ratings of counseling ability were positively associated with the degree to which a counselor's written reports of personal incidents suggested that he possessed certain qualities characteristic of self-actualized persons. Foulds (1969) likewise obtained overall modest positive correlations between self-report measures of self-actualized functioning and judges' impressions of counseling-facilitation levels offered to clients.

The group setting's practicality has made it a popular vehicle for incorporating experiential modes of learning and personal development into training curricula, and positive sequelae to such groups have been reported in two studies (Betz, 1969; Gazda & Ohlsen, 1961).

¹ This report is based on data collected as part of an in-service training program for secondary school counselors funded to the second author by the New York State Bureau of Guidance and sponsored by the Capital District Personnel and Guidance Association of Albany. First and second authorship was determined by a coin toss.

Requests for reprints should be sent to Stephen I. Abramowitz, Interuniversity Psychological Counseling Center, 300 Oxford House, 1313 21st Avenue South, Nashville, Tennessee 37212.

Extrapolation of the group experience concept to the in-service training of counselors has been urged by Truax and Mitchell (1971). The aim would be "to reinforce the habit of relating to clients with high levels of interpersonal skill and to discourage the counselor's tendency to fall back into his lifelong style of relating to others [p. 340]." Accordingly, the present investigation was undertaken to assess the personal and professional outcomes of such an in-service training workshop for secondary school counselors. Participants received intensive instruction in the core dimensions of facilitative interpersonal process (Carkhuff, 1969) and either an interpersonally oriented group experience in the encounter motif or one structured around deep relaxation and other intrapersonal concentration exercises. Hence, in addition to an overall evaluation of the program's effectiveness, determination of the differential merits of these two contrasting approaches to promoting personal development was possible.

Method

SUBJECTS AND PROCEDURE

Thirty-five secondary school counselors expressed a desire to enroll in an in-service training workshop sponsored by the Capital District Personnel and Guidance Association and conducted by Union College Counseling Center staff and consultants. The counselors represented 11 school systems and a broad spectrum of orientations. Age and experience ranges were from 21 to 53 years and from 1 to 30 years, respectively. From two to six pupil-clients of each prospective inductee also participated in the research.

Fortuitously from an experimental standpoint, about one third of the original training seekers had schedules that could not be accommodated within the workshop's time framework, providing a control group against which to compare the performance of persons exposed to either of the two experimental conditions. Those individuals able to attend the training sessions were assigned randomly to the intrapersonal self-control group or to the interpersonal encounter group.

Each counselor in the experimental treatments received up to ten 3-hour training sessions held over a 3-month period. Half of each meeting was devoted to intensive didactic-based learning in the core facilitative constructs of empathy, regard, genuineness, concreteness, and self-disclosure (Carkhuff, 1969). In addition, self-control trainees were exposed to 15 hours of deep relaxation experiences, whereas their interpersonal encounter counterparts were offered 15 hours of sensitivity experiences (Otto, 1970). The prescribed orientation for the former group was the development of the creative imagination for problem solving through the achievement of deeper levels of physical and mental relaxation. To illustrate, during one meeting members were given the following suggestion: "When you meet with your client and take several deep breaths, you will experience a deep sense of relaxation, physically and mentally. In this state of deep relaxation, you will be receptive to what your client is thinking and feeling. Each time you respond to your client, you will be functioning at very high levels of the facilitative dimensions."

By contrast, the goal of the sensitivity awareness group was to promote more authentic and meaningful interpersonal

relationships within and outside the group via examination of one's interactions in both settings. As an exercise exemplar, members role-played various group and family interactions, alternately assuming the parts of placator, preacher, avoider, blamer, and real-self, and then explored their reactions (Satir, 1972).

Both treatment groups were directed by the same PhD psychologist, who was familiar and comfortable with both approaches. He and the two psychologists (one PhD, one MA) who orchestrated the Carkhuff-based didactic component of the workshop were each regarded as high therapy-facilitators in the client-centered sense and were accustomed to earning ratings of 4 on the standard 5-point continuum of empathic communication (Carkhuff, 1969).

Pretesting occurred during an orientation session in which the counselors were introduced to the training staff and materials. Posttraining data were gathered at the close of each group's final meeting. Counseling process data were collected anonymously by a neutral party from the workshop participants' clients before and after the counselors' immersion in the in-service training program.

INSTRUMENTS

Personal Orientation Inventory (POI). This measure was employed to assess the degree to which the counselors' personal qualities met the criteria for positive mental health articulated within self-actualization theory (Maslow, 1954; Shostrom, 1966). For each of the Inventory's 150 statement pairs, the respondent selects the more self-descriptive alternative. Although few data pertinent to the psychometric adequacy of the POI's component scales are yet available, the evidence suggests that they discriminate reasonably well between persons functioning at differential levels of experiential well-being (Shostrom, 1966).

Tape Excerpt Response Procedure (TERP). The counselors' ability to communicate empathically was gauged, in vitro, by an adaptation of the TERP (Selfridge et al., 1972), consisting of eight simulated interview scenes presented on videotape. This version of the TERP demonstrated construct validity in previous research with trainees (Abramowitz, Abramowitz, Weitz, & Hester, 1974). Each half-minute excerpt depicts an individual whose verbal or nonverbal behavior suggests psychological distress. Immediately after projection of each segment, the subjects responded in writing with their most helpful reaction to the hypothetical client.

Mixed together and group-unspecified, the pre- and post-protocols were rated by six trained judges along the standard 5-point scale of empathic understanding. A reasonable level of interrater concordance was indicated by a Kendall coefficient of concordance (W) of .70 ($p < .01$) derived from the judges' evaluations of a selected response form.

Relationship Orientation Inventory (ROI). The ROI was completed by the participants' long-term counselees to provide an index of the counselors' relatability from the client's perspective. This well-known instrument is comprised of four 16-item completely counterbalanced subscales designed to tap the Rogerian dimensions of regard, empathy, unconditionality, and congruence (plus global relationship quality; Barrett-Lennard, 1962). In recent research utilizing the revision of the ROI used here, the estimated reliability (coefficient alpha) of each component scale exceeded .75 and the estimated reliability of total relationship scores was .92 (Abramowitz & Jackson, 1974). A counselor received the mean of the scores given by all of his originally designated clients, who also returned a postworkshop form.

Additional variables. Demographic and consumer satisfaction data were also gathered.

SATISFACTION WITH TRAINING PROGRAM

Several questions written to tap the degree to which the workshop participants (excluding controls) considered their training experience to have been worthwhile formed part of the postbattery. To assure anonymity and thereby reduce the likelihood of artificially inflated evaluations, this section of the questionnaire was administered separately, uncoded by condition or name. Appraisals were uniformly enthusiastic, as indicated by the following representative mean ratings from a strongly disagree-strongly agree (1-5) Likert response continuum: I was able to gain information about myself, 4.6; I have deepened and broadened my personal horizons, 4.2; I have become more sensitized to problem areas within myself, 4.4; I feel encouraged to tackle problem areas within myself, 4.4; I was able to resolve conflict within myself, 3.8; My clients have benefited from my training, 4.1; and, Everything considered, I am satisfied with the results of my training experience, 4.5.

MAIN RESULTS: COMPARATIVE TRAINING OUTCOMES

The randomness of a counselor's assignment to an experimental condition was constrained by scheduling conflicts, the subsamples themselves were modest in size, and some attrition occurred. Hence, checks were made to insure unbiased distributions within the resulting subgroups. No significant between-condition differences were revealed by any of the one-way analyses of variance done on the change-criteria prescores, tending to discount subject artifacts as confounds. Data reflecting on the impact of the program on the participants' personality and ability to communicate facilitatively were submitted to *t* tests appropriate when both sets of measures are taken on the same subjects.

Trainee self-actualization. Descriptive data and analysis summaries by training condition are shown for each POI scale in Table 1. Inspection of the information exhibited suggests that both the self-control and encounter workshops tended to promote members' personal growth relative to that of individuals whose previous time commitments precluded their enrollment in the program. In general, however, the most impressive gains were registered in the deep relaxation group. Counselors exposed to the concentration exercises evinced improvement in time competence ($p < .05$) and inner directedness ($p < .05$), the POI's two main indexes, as well as in self-actualizing value ($p < .05$), acceptance of aggression ($p < .01$), and capacity for intimate contact ($p < .05$). On the other hand, sensitivity workshop participants' existentiality ($p < .05$), feeling reactivity ($p < .05$), and spontaneity ($p < .01$) were enhanced. The self-acceptance postscores of the controls were significantly higher than their prescores ($p < .05$); this was largely a function of within-

group consistency in, rather than size of, gains on this measure.

Trainee facilitativeness. Descriptive data and analysis summaries by subgroup are presented for the TERP in Table 2 and for the ROI in Table 3. Data yielded by the simulated clinical interview situations indicate that counselors undergoing both training programs, but not the controls, responded more empathically to the

* $p < .01$, one-tailed.

hypothetical help-seeker after the program's completion ($p < .01$, in both cases). However, from the clients' vantage point (Table 3), the deep relaxation techniques were generally more effective than interpersonal encounter experiences in honing counselors' relationship skills. Counselors instructed in self-control were perceived as having become more empathic ($p < .05$), more unconditional in their expressions of regard ($p < .05$), and more facilitative overall ($p < .05$). The small increment in unconditionality among the control subjects ($p < .05$) was the only other statistically reliable result from the ROI. In neither case in which significant change in the level of a therapist-offered condition was detected for more than one treatment group was the amount of change differential.

Discussion

Marked improvement in the ability to communicate empathically, in vitro, was forged in both workshops,

although, according to the clients, radiation of this skill to actual counseling interviews was confined to relaxation-concentration group members. Participants also showed gains in various aspects of self-actualization, this progress again most striking among members of the self-control rather than the interpersonal-sensitivity group. That these person-outcomes are on occasion transmitted to work associates not exposed directly to training is suggested by the incidental increments in functioning posted by the controls. Longer-term follow-up unfortunately lies beyond the study's scope, leaving open the issue of the extent to which the new learning will, with time, succumb to the comfort of old habits. Nevertheless, the evaluation's ground-breaking implication is that substantial enthusiasm and discernible self-development and skill acquisition can be stimulated among practicing counselors by a relatively brief, inexpensive training module.

The slight but overall superior effectiveness of the self-control techniques is intriguing and warrants exploration. One distinction between the intrapersonal and the interpersonal workshops was the degree to which, in the former, particular reference was made to actual counseling situations, perhaps accounting for self-control participants' exclusively raised posttraining relationship ratings from clients. Related research has identified "job-related" facets of training as performance predictors (Paul, McInnis, & Mariotto, 1973). The relaxation-concentration exercises' generally greater potency could, however, also be attributed to their relative novelty or to an interaction of the hypnoticlike suggestions of the workshop leader (a charismatic individual) and counselors' trustfulness. Whether such a program emphasis would be as successful among PhD practitioners cast in the intellectual-skeptical mold is a question for future research to address.

Another interpretive task is to explore the possible reasons for the muted benefits accruing to counselors who underwent the interpersonal relations experience. Despite its avowed focus, this condition failed to inspire positive movement along the ROI's two "interpersonal sensitivity" dimensions (acceptance of aggression and capacity for intimate contact; Shostrom, 1966), whereas the self-control condition did promote such growth. This opaque but sobering finding is consistent with other recent data hinting that the effects of sensitivity training on relations with others are less spectacular than sometimes claimed (Hurley & Force, 1973; Lieberman, Yalom, & Miles, 1973).²

Visual inspection of the interpersonal-encounter

² However, in another investigation (Selfridge et al., 1974), an encounter group proved to be a relatively successful in-service training modality. Interestingly, in that study, the encounter experience provided a learning context more (rather than less) similar to the actual counseling situation than that offered by the alternative training condition (i.e., didactic).

group's descriptive data revealed several instances wherein increased postworkshop variability prevented the realization of statistical significance and masked otherwise sound gains (e.g., inner directedness on POI, total relationship on ROI). Subsequent analysis disclosed flat or mildly negative reactions among two persons who entered the training program conspicuously less self-actualized (on the POI) than their fellow group members. Previous evidence (Carkhuff, 1969) also intimates that less well functioning persons are the least responsive to didactic-experiential training. However, more fully functioning self-control workshop members did not demonstrate differentially favorable outcome relative to lower-POI starters.

No group of counselors underwent didactic-based training in facilitative interpersonal process *only*, without an adjunctive experiential component. This imposes a formidable constraint on our freedom to pinpoint sources of gain (i.e., didactic versus experiential), except in those comparatively few instances of differential intrapersonal-workshop versus interpersonal-workshop impact. Thus, a substantial part of the program's success could well have been due to the primarily didactic-plus-role-playing training in the core conditions or to elements common to both experiential encounters (e.g., leader personality, group cohesion, etc.). The noteworthy increase in the ability of all program participants to respond empathically to contrived help-seekers (on the TERP) playing roles similar to those enacted as part of the training in facilitative offering once again seems to highlight the importance of congruity between job and training situation in promoting transfer of training gains (cf. Paul et al., 1973).

The absence of independent observations as checks to ascertain that the leader of the experiential modules did, in fact, structure them as prescribed (cf. Roback, 1974), the notorious unreliability of process notes (which were available), and the possibility of condition-differential facilitator expectations of success (cf. Goldstein, 1962) combine to discourage conjecture at finer levels of analysis. Attention to such lacunae would seem a reasonable expectation of future evaluators concerned with whether educators, administrators, and on-line service deliverers can collaborate in offering, at moderate cost, a stimulating training experience whose sequelae are detectable by standard assessment devices.

Fellowships and Postdoctoral Programs

American Association for the Advancement of Science: Announces a

program supporting up to 10 outstanding advanced graduate students in the social and natural sciences as intern reporters, researchers, or production assistants in a variety of media for the summer of 1975. Salaries will be paid by AAAS at a level based on the current rate for interns in the participating media. Travel expenses are paid also. *Deadline for receipt of completed applications is February 1, 1975.* For information, contact Wendy Weisman-Dermer, Communications Office, AAAS, 1776 Massachusetts Avenue, N.W., Washington, D.C. 20036.

Cleveland Metropolitan General Hospital, Departments of Psychiatry and Pediatrics: Now accepting applications for predoctoral internships in clinical psychology (combined adult and child program) for 1975-1976. Stipend \$7,000 plus \$600 per dependent up to two dependents. *Apply before January 10, 1975*, to John Shen, Department of Psychiatry, Cleveland Metropolitan General Hospital, 3395 Scranton Road, Cleveland, Ohio 44109.

Cornell University, New York State College of Human Ecology: Now accepting applications for graduate assistantships in applied areas of the social and behavioral sciences. For information, write to Director of Graduate Studies, N116 MVR, New York State College of Human Ecology, Cornell University, Ithaca, New York 14853.

Department of Psychiatry, Mount Zion Hospital and Medical Center, San Francisco: Three intensive advanced postdoctoral programs in psychology: (a) child or adult community mental health, (b) psychother-

Department of Psychiatry, Mount Zion Hospital and Medical Center, San Francisco: Now accepting applications for 1975-1976 one-year predoctoral fellowships in clinical psychology and in clinical child psychology. *Deadline for applications is January 1, 1975.* For further information, write to Donald P. Cliggett, Mount Zion Hospital and Medical Center, 1600 Divisadero Street, San Francisco, California 94115.

Division of Clinical Psychology, Upstate Medical Center, State University of New York at Syracuse: Now accepting applications for APA-approved internships in clinical psychology for 1975-1976: both clinical-adult and clinical-child predoctoral internships. Stipends \$6,000. For more information, write to Sidney A. Orgel, Division of Clinical Psychology, Upstate Medical Center, 750 East Adams Street, Syracuse, New York 13210.

Section of Clinical Psychology, University of Manitoba School of Medicine: Now accepting applications for predoctoral internships in clinical psychology for 1975-1976. Stipend \$8,000. For further information, write to Robert H. Martin, or Robert de von Flindt, Section of Clinical Psychology, Faculty of Medicine, University of Manitoba, 770' Bannatyne Avenue, Winnipeg, Manitoba, R3E 0W3.

Explore the mind of today's man with Wiley-Interscience Books

1. Drugs and Behavior:

A Primer in Neuropsychopharmacology

By Ernest L. Abel, *New York State Department of Mental Hygiene*

Written for graduate and undergraduate students of various backgrounds, this book clearly outlines the nature of drug action from the absorption of drugs into the body through final elimination. It discusses the various factors influencing this process from the context of the nervous system and drug-receptor theory.

1974 approx. 256 pages \$13.95

2. Innovations in Client-Centered Therapy

Edited by David A. Wexler, *University of California San Francisco*, and Laura North Rice, *York University, Ontario*

This volume of original papers provides an in-depth view of new developments in client-centered therapy. It gives readers a detailed picture of contemporary theory and practice in client-centered thought. In addition, the book extends client-centered thinking to a broader social context—showing how its principles can be used in society to promote individual and social change.

A volume in the Wiley Series on Personality Processes, edited by Irving B. Weiner

1974 approx. 544 pages \$22.50

3. The First Year of Bereavement

By Ira O. Glick, *Ira O. Glick & Associates, Inc.*, Robert S. Weiss, *Harvard Medical School*, and C. Murray Parkes, *The Tavistock Institute of Human Relations, London*

Based on a detailed statistical study, this book provides an accurate picture of the first year of bereavement as seen through the eyes of fifteen widows under the age of forty-five. The book follows the widows through successive phases of adjustment, paying particular attention to their social relationships, what they saw as helpful or harmful during this critical period, and how they established their paths of recovery or failure.

1974 approx. 336 pages \$12.50

Following Books are Forthcoming.

4. Origins of Fear, Volume 2

Edited by Michael Lewis, *Educational Testing Service*, and Leonard A. Rosenblum, *State University of New York Downstate Medical Center*

Showing how fear represents the conflux between the infant's emerging cognitive and affective systems, this book provides both ontogenetic and phylogenetic perspectives. Its chapters reflect the integration of original papers, critical comments, and thematic discussions from a conference supported by the Educational Testing Service, Princeton, New Jersey. Topics covered include infant's reactions to people, fear-mediated processes in the context of imprinting, and fear and the development of social attachments in the first year of life.

1974 approx. 384 pages \$17.95

5. The Volunteer Subject

By Robert Rosenthal, *Harvard University*, and Ralph L. Rosnow, *Temple University*

This is the first comprehensive review of the literature on employing volunteer subjects in behavioral and social research. Dealing with the topic from both a methodological and ethical point of view, it thoroughly covers situational determinants, causal inferences, reducing or eliminating artifacts, and procedures for increasing external validity. In addition, it helps readers cope with the problem of the volunteer subject by providing an overview of general problems and a thorough, constructive set of alternatives for dealing with them.

A volume in the Wiley Series on Personality Processes, edited by Irving B. Weiner

1974 approx. 288 pages \$13.95 (tent.)

6. Research Strategies in Psychotherapy

By Edward S. Bordin, *University of Michigan*

For researchers or potential researchers in the field of psychotherapy, this book offers a critical appraisal of previous work . . . provides a guide to research methodology . . . and helps identify the important questions they should address in the future. Providing an unusually broad compass of theoretical positions, the book pinpoints important research issues and deals with many down-to-earth practices for carrying out psychotherapy.

A volume in the Wiley Series on Personality Processes, edited by Irving B. Weiner

1974 approx. 288 pages \$16.95

Thesaurus of Psychological Index Terms

Contains over 4,000 terms representing an authoritative, unambiguous, and hierarchically structured vocabulary used by psychology and related disciplines. This vocabulary will facilitate precise content representation of concepts described in psychological literature and allow for more flexibility in automated search and retrieval operations. These two factors promote more effective communication of psychological concepts in original works and research, ultimately aiding the content of publications to be focused in accordance with the interest patterns of psychologists.

This **Thesaurus**, developed by the Psychological Abstracts Information Services, is divided into three sections:

The **relationship section** shows the relationships among concepts that are associated with each other. Term relationships noted are: synonymous, broader, narrower, or related.

The **alphabetical section** presents each preferred term in alphabetical order, enabling rapid identification of terms used for indexing.

The **hierarchical section** contains 17 broad content areas in which terms are presented in descending order according to breadth of concept represented. The 17 categories correspond to major classifications used in *Psychological Abstracts*.

The relationship, alphabetical, and hierarchical sections will assist the user in selecting appropriate terms for different uses.

Administrators

- determine areas of research for an organization
- assure representative expertise in personnel selection

Researchers and Authors

- find synonyms for a term representing a concept
- select terms that represent a concept
- define subject matter topics for a paper or book

Educators

- structure a curriculum
- use as a tutorial aid

Consultants

- search the literature
- aid in retrieval of information

Librarians

- provide access to psychological literature
- aid in cataloging psychology material
- aid in ordering new psychological literature

Students

- locate concepts relevant to psychology
- focus areas of study

The **Thesaurus** contains 362 pages with a hard-cover and costs \$12. Please note that all orders amounting to \$15 or less must be accompanied by full payment except for those orders submitted on institutional purchase order forms.

THE

texts

Psychology: An Introduction to Human Behavior

Morris K. Holland, *University of California, Los Angeles*
1974 Cloth 560 pages

An introductory text carefully attuned to student interests and experiences. Geared to motivate readers, the book presents the traditional content of psychology within the framework of provocative life themes—drugs, aggression, war, love and sex, mind control, revolution, and others. Ten optional methods sections introduce readers to the ways psychologists think about problems and the procedures used in investigations. An informal, conversational tone, a clear writing style even in discussions of more advanced concepts, and a striking use of original graphics involve students verbally and visually. Student Workbook. Instructor's Manual. Individualized Study Program. Test Item File.

Psychology: An Introduction

Paul Mussen and Mark R. Rosenzweig, *University of California, Berkeley*; Elliot Aronson, *University of Texas*; David Elkind, *University of Rochester*; Seymour Feshbach, *University of California, Los Angeles*; P. James Geiwitz, *University of California, Santa Barbara*; Stephen E. Glickman, *University of California, Berkeley*; Bennet B. Murdock, Jr., *University of Toronto*; Michael Wertheimer, *University of Colorado* 1973 Cloth 847 pages

An exceptionally accurate reflection of current theories and research in psychology. Each section author, a recognized expert in his field, provides a clear analysis of the past, present, and future trends of his specialty. Reversing the usual sequence of topics, the text begins with areas most akin to students' life experiences—social psychology and personality. Three-page sections in full color depict Art and Psychology, Perception, and Biological and Comparative Psychology. Technical terms are introduced and defined with care for the student with no background in psychology. Instructor's Manual. Student Workbook. Individualized Study Program. Test Item File.

readers

JUST PUBLISHED

Readings in Perception: Principle and Practice

Peter A. Fried, *Carleton University*
September 1974 Paper 560 pages

A collection of readings acquaints students with some of the most influential theories and issues in perception. The book is divided into three parts, each containing a balance of classical and contemporary research. The first deals with stimuli and intervening variables; the second with perceptual learning and physiological mechanisms underlying perception; the third with higher processes such as memory and individual differences.

Aldine Psychology Books

New in 1974 —

THOUGHT AND FEELING

**Cognitive Alteration
of Feeling States**

edited by Harvey London
and Richard E. Nisbett

This book consists of experimental studies that derive from and extend Schachter's theory of emotional states and Heider's attribution theory. The papers deal with a wide variety of topics — for example, aggression, boredom, obesity, the control of pain, delusional systems. Each of the authors takes the theoretical concept of cognition and relates it to research he is currently doing in biofeedback, physiology, social psychology, altered states of consciousness, etc. Thus the book provides a summary of the present state of cognitive research that will serve as a benchmark for future work on the subject.

164 pp. April 1974 \$8.95 cloth

CARDIO- VASCULAR PSYCHO- PHYSIOLOGY

**Current Issues
In Response Mechanisms,
Biofeedback
and Methodology**

edited by Paul A. Obrist,
A.H. Black, Jasper Brener
and Leo V. DiCara

This book — containing original papers by the leading authorities on the subject — offers the first comprehensive overview of the entire field of cardiovascular psychophysiology. The book includes a summary by the four editors, discussing the goals of research on the psychophysiology of the cardiovascular system and the appropriate strategies for achieving these goals. A remarkable bibliography of nearly 1,000 items provides the first comprehensive guide to the output of research workers in this rapidly growing field.

640 pp. September 1974 \$19.50 cloth

CLINICAL PSYCHOLOGY

**The Study
of Personality
and Behavior**

Sol L. Garfield

"In a period when the entire field is in flux it is good to have an authoritative statement about clinical psychology. I have read the book with interest and find it accurate and well written. Dr. Garfield probably knows as much about our profession as anyone and is able to see developments in a historical context. His book should be a useful source for introductory courses in clinical psychology."—Alan O. Ross, Professor, Psychological Center, State University of New York, Stony Brook

456 pp. March 1974 \$14.95 cloth

\$8.95 paperbound text edition for classroom use only

Aldine Standards —

BEHAVIOR: THE CONTROL OF PERCEPTION

William T. Powers

A 1974 National Book Award nominee in The Sciences

"Gives social scientists — finally — an alternative to both behaviorism and psychoanalysis. It provides a way, both elegant and sophisticated, to include the basic contributions of both without being partisan or converted. We now know much more than we did before this book was published"—Paul J. Bohannon, Stanley G. Harris Professor of Social Science, Northwestern University

320 pp. 1973 \$8.95 cloth

SEXUAL CONDUCT

**The Social Sources
of Human Sexuality**

**John H. Gagnon and
William Simon**

"Gagnon and Simon have provided me with the kind of intellectual excitement one enjoys all too seldom. They have integrated disparate bits of data from diverse disciplines into a set of provocative hypotheses about the nature of human sexual development. There is no question that the book will be a classic."—Gerald C. Davison, Professor of Psychology, SUNY, Stony Brook

328 pp. 1973 \$8.95 cloth

HYPNOSIS

**Research Developments
and Perspectives**

**edited by Erika Fromm
and Ronald E. Shor**

"The work is a 'must' not only for every serious researcher, but also for the practicing clinician . . . the book is one of the most significant contributions to the field ever published and should serve as a basic reference for some time to come."—John G. Watkins, Professor of Psychology, University of Montana, *International Journal of Clinical and Experimental Hypnosis*

544 pp. 1972 \$27.50 cloth

IMAGE AND ENVIRONMENT

**Cognitive Mapping
and Spatial
Behavior**

**edited by Roger M. Downs
and David Stea**

"Through this most attractive book, coedited with unusual care, we find ourselves at the frontier of a new and exciting intellectual domain, that of the individual's conception of his geographic environment. Downs and Stea deserve nothing but praise. This is, in short, a volume to which those in the growing field of environment-and-behavior will turn frequently, as much from necessity as for enjoyment and profit."—Joachim F. Wohlwill, Division of Man-Environment Relations, Pennsylvania State University, University Park, Science

461 pp. 1973 \$15.00 cloth

Psychology Lives!

... in Saunders texts...

Millon & Millon: Abnormal Behavior and Personality

A Biosocial Learning Approach

The origins, development and functions of abnormal behavior are examined in the light of social learning theory in this introductory text. The authors' approach differs from other social-learning models in their recognition of individual biological tendencies as determinants of behavior, and in their coverage of abnormal personalities in everyday life—thus establishing continuity between milder pathologies and more severe disorders. By **Theodore Millon and Renee Millon**, Univ. of Illinois. 535 pp. *Illustd.* \$11.95. Feb. 1974.

Order #6390-7.

An Instructor's Manual is available.

A Study Guide, by **Lella Foster and Theodore Millon**, highlights important theories and briefly summarizes each chapter of the Millon & Millon text. Review questions are included. 112 pp. \$3.50. Feb. 1974.

Order #3819-8.

Millon: Theories of Psychopathology and Personality

Essays and Critiques—2nd Edition

Fifty-nine of the world's most respected clinicians and theorists make the second edition of this popular anthology a truly authoritative sourcebook. Papers are grouped according to the type of data they emphasize: biophysical, intrapsychic, phenomenological, behavioral, sociocultural, and integrative. Edited by **Theodore Millon**. 502 pp. Soft cover. \$5.95. April 1973.

Order #6382-6.

Johnson: Aggression—In Man and Animals

Aggressive behavior in more than 150 species is described here, but the emphasis is on man—his guns, drugs, racial tensions, televised violence and war. It's a hard-hitting text applicable to almost any undergraduate psychology course. By **Roger N. Johnson**, Ramapo College, N. J. 269 pp. *Illustd.* Soft cover. \$4.50. April 1972.

Order #5180-7.

Voeks: On Becoming an Educated Person—3rd Edition

One of the best guides available on teaching students how to learn—through proper study habits, attention, and attitudes. By **Virginia Voeks**, San Diego State College. 278 pp. *Illustd.* Soft cover. \$2.95. June 1970.

Order #9068-1.

DiCaprio: Personality Theories Guides to Living

This life-oriented approach to the study of personality analyzes the views of major theorists as applied to specific aspects of personality—development, learning, needs and motivation, conflict, and the search for "the good life." The material both fosters an understanding of individual behavior and relates directly to everyday living, making it uniquely adaptable for use in adjustment courses as well as personality courses. By **Nicholas S. DiCaprio**, John Carroll Univ., Cleveland. 502 pp. *Illustd.* \$10.95. July 1974.

Order #3055-3.

An Instructor's Manual is available.

Shope: Interpersonal Sexuality

General and developmental aspects of human sexuality are fully described, with an emphasis on interpersonal relationships and psychosocial functions rather than genital sex. Special consideration is given to premarital sex, sexuality and morality, and children's sexual development. Designed for courses in human sexuality, it's an excellent auxiliary text for behavioral science as well. By **David F. Shope**, Pennsylvania State Univ. About 385 pp. About \$7.50. Ready January.

Order #8253-7.

Sattler: Assessment of Children's Intelligence

The complete spectrum of intelligence testing in children is covered here in a single volume. It shows how to best administer tests; how to use them to evaluate mental disorders, mental retardation or learning disabilities; and how to most effectively test minority group children. Major coverage is of the Stanford-Binet and Wechsler (WISC/WPPSI) batteries, though others are included. An upcoming reprint of the text will also include coverage of the WISC-R and the 1972 Binet norms. By **Jerome M. Sattler**, San Diego State Univ. About 575 pp. About \$14.95.

Order #7944-7.

Kaufmann: Introduction to the Study of Human Behavior

Here's valuable supplementary reading for introductory courses in personality, social psychology, and educational psychology. Dr. Kaufmann examines the rationale for, and the methods used in the scientific study of human behavior. By **Harry Kaufmann**, Hunter College, CUNY. 162 pp. *Illustd.* Soft cover. \$2.50. April 1968.

Order #5300-6.

MEASUREMENT AND CLASSIFICATION OF PSYCHIATRIC SYMPTOMS

J. K. WING, J. E. COOPER
and N. SARTORIUS

This book defines the experiences that constitute psychiatric symptoms, with the aim of reducing the subjective element in diagnosis, and describes an interview technique through which the symptoms can be reliably recorded. The appendix, "Present State Examination", is a comprehensive interview schedule providing a means of standardizing the elements of psychiatric diagnosis and is available as a separate booklet. "It is my feeling that this book will attract potentially a large readership in every field of psychiatry . . . I consider it a valuable piece of work in which, so to speak, a microscope is being used for the first time instead of a magnifying glass."—Dr. Phillip Polatin, *Professor Emeritus of Clinical Psychiatry, College of Physicians & Surgeons, Columbia University*

HUMAN INTEREST yields the highest return

A New Book! HUMAN DEVELOPMENT: The Span of Life. This new text uniquely covers the entire life cycle—from conception through old age and death. Descriptive in approach, it presents emotional, moral and social factors. By **GEORGE KALUGER, Ph.D.**; and **MERIEM FAIR KALUGER, Litt. M. May, 1974. 342 pp., 44 illus. \$10.50.**

A New Book! HUMAN EXPERIENCE: A Psychology of Growth. Topics explored in this new text include: adjustments to dramatic changes in lifetime styles; relationships and conflict; etc. By **RONALD G. POLAND, Ph.D. February 1974. 240 pp., 31 illus. with graphic abstractions by KAREN SWEIK-HARDT. \$8.50.**

A New Book! INTERVENTION IN HUMAN SERVICES. The first human service training text to focus on skills development, this book covers observation skills, recording, and reporting, and interviewing and counseling. By **EVELINE D. SCHULMAN. June, 1974. 248 pp., 24 illus. \$6.95.**

New 2nd Edition! CRISIS INTERVENTION: Theory and Methodology. A comprehensive overview of crisis intervention includes therapeutic groups, group therapy, and two crisis group studies. By **DONNA C. AGUILERA, R.N., M.S.; and JANICE M. MESSICK, R.N., M.S. April, 1974. 168 pp., 13 illus. \$6.00.**

PSYCHOLOGY

—WINTHROP—

is proud to announce
its first publications in Psychology

**For students asking...Why psychology?
What is it? What can it do?**

Psychology: A New Perspective

by Dalmas A. Taylor and Sidney A. Manning
University of Maryland and Federal City College

Approaches the introductory course from the framework of current issues of concern and interest to the student — social power and conformity, psychosurgery and behavior control, prejudice and racism — and at the same time presents the basic concepts and data essential to a good understanding of introductory psychology. Presents psychological data in a short, concise form which is easily comprehended by introductory students as well as offers maximum flexibility in presentation for the teacher. To minimize the confusion inherent in technical language at the introductory level, the book offers a glossary of statistical and conceptual definitions at the end of each division.

Instructor's Guide available.

January 1975 400 pp.

For students of Social Psychology

An Introduction to Attribution Processes

by Kelly G. Shaver
College of William and Mary

Why do people act the way they do? How do their desires and fears become known to us? These are questions that attribution theory tries to answer. In a readable, informal style, Kelly Shaver provides a thorough introduction to attribution for any reader with a desire to increase his understanding of the causes of human behavior. No attempt is made to present a comprehensive review of experimental research; the studies chosen merely serve to explain principles previously set forth in the book. Theoretical principles and issues are illustrated by familiar examples.

WOMEN: A Feminist Perspective

Edited by JO FREEMAN

State University of New York College, Purchase

Going well beyond the emotional rhetoric of the early feminist movement, this volume presents a collection of penetrating, scholarly essays on women by women from a wide range of academic disciplines. Drawing on the emerging body of substantive research on women and employing traditional scholarly disciplines, psychologists, sociologists, political scientists, and lawyers among others thoughtfully assess the effects of sexism, document the status of women, and analyze the complex institutions and values that keep women in their place.

January 1975 470 pages paper approx. \$7.00

THREE WORLDS OF THERAPY

An Existential-Phenomenological Study of the
Therapies of Freud, Jung and Rogers

ANTHONY BARTON, Duquesne University

Barton vividly and concretely describes in understandable terms the three well-known forms of psychotherapy created and developed by Freud, Jung, and Rogers and demonstrates how each is a plausible therapeutic method. To illustrate how each method works and how each differs from the other two, Barton takes the same 32-year old female patient, Mary, through each form of analysis. He shows how Mary reacts differently to each method and how and why the outcome is variable. *The best book on the theory and practice of psychotherapy I have ever read. I hope every person who is planning to enter the field of psychotherapy or who is now in the field will read it. To read it is a superb learning experience.*—Calvin Hall, co-author, "Theories of Personality"

1974 271 pages cloth \$8.95 paper \$4.95

ISSUES IN SOCIAL ECOLOGY

Human Milieus

Edited by RUDOLF H. MOOS and PAUL M. INSEL
Stanford University

This is an up-to-date collection of articles that cover such topics as: theory and design, physical forces and social behavior, population density and the use of space, man-made designs and psychosocial consequences, behavior settings and psychosocial interaction, organizational structure and social behavior, characteristics of the milieu inhabitants, psychosocial climate and environmental press, reinforcement contingencies and social behavior, and person-environment fit. *An invaluable work which should prove a milestone in the history of environmental psychology.*—John Monahan, University of California, Irvine

1974 616 pages cloth \$11.95 paper \$7.95

Mayfield Publishing Company

285 Hamilton Avenue / Palo Alto, California

AMERICAN PSYCHOTHERAPY SEMINAR CENTER

Annual Conference
New York City
December 7-8, 1974

Topic:

"Working with the More Difficult Patient"

Participants:

Leopold Bellak, M.D.
Peter Giovacchini, M.D.
Edith Jacobson, M.D.
Otto Kernberg, M.D.
Stanley Lesse, M.D.
Theodore Lidz, M.D.
Herbert Rosenfeld, M.D.
Lyman Wynne, M.D.

The conference will attempt to reflect the actual setting of the consultation room and the actual dialogue between therapist and patient.

There will be an opportunity to observe first-hand actual patient interviews and discuss with participating therapists their techniques and theoretical rationale.

Live patient interviews, case presentation, small group workshops and discussion groups. Early registration is urged.

789 West End Avenue
New York, New York 10025

COGNITION AND BEHAVIOR MODIFICATION

Michael J. Mahoney, Pennsylvania State University

A well-reasoned argument for applying scientific techniques to the study of human cognition. After examining some of the conceptual and philosophical issues regarding inference and cognitive-symbolic processes, Mahoney undertakes an empirical evaluation of the two mediational models—"covert conditioning" and "cognitive learning". The final section suggests some tentative clinical implications of cognitive behavior modification and offers a general paradigm for therapeutic science. 389 pp \$13.50

THE EFFECTIVENESS OF DRUG ABUSE TREATMENT

edited by Saul B. Sells, Institute of Behavior Research,
Texas Christian University

The most extensive source of information available on addicts and habitual users of illegal drugs, the types of treatment provided for them, and the effectiveness of various treatments for different types of patients. This two-volume work reports the findings of the long-range Drug Abuse Reporting Program (DARP) of the National Institutes of Mental Health.

VOL. I: EVALUATION OF TREATMENTS
570 pp \$18.50

VOL. II: PROFILES ON PATIENTS, TREATMENTS
AND OUTCOMES 442 pp \$16.50

Note: THE REGULATION OF ENCOUNTER GROUPS, by Daniel Hogan, International Association of Applied Social Scientists, will be published by Ballinger early in 1975.

For more information on these and related Ballinger titles, please write for our catalog.

Announcing the new edition of the introductory textbook that needs no introduction

Introduction to Psychology

Sixth Edition

ERNEST R. HILGARD, RICHARD C. ATKINSON,
and **RITA L. ATKINSON** all of Stanford University

A major, thorough revision of a classic textbook, this new Sixth Edition of *Introduction to Psychology* is "even better than the Fifth Edition—more readable, more relevant, more exciting."* It reflects the latest and most important research in traditional areas as well as on topics of particular interest today, yet it carefully maintains those aims and features—superb scholarship, comprehensive coverage, clarity, interest, and accuracy—that have always distinguished *Introduction to Psychology*. Among the many special features of the Sixth Edition:

- A new opening section on five key psychological conceptions of human nature—neurobiological, behavioral, cognitive, psychoanalytic, and humanistic—that lays the groundwork for stimulating discussions throughout the book
- A reconceptualized and rewritten section on "Motivation and Emotion" reflecting the most current research and theory
- Collaboration with the well-known social psychologist Daryl J. Bem on the exciting new concluding chapters—"Social Psychology" and "Psychology and Society"
- Thoroughly revised and expanded chapters on the "Biological Basis of Psychology," "Developmental Psychology," and "States of Consciousness"
- The inclusion of a number of fascinating, informative new case studies in the chapter on "Psychopathology"
- An increased emphasis on cognition, including new material in the highly regarded section on "Learning and Thinking"

Completely redesigned in a striking new format, and with a vastly expanded illustration program of more than 500 charts, graphs, and photographs, the Sixth Edition of *Introduction to Psychology* is certain to enhance the Hilgard, Atkinson, and Atkinson reputation for introductory psychology at its best. 672 pages (probable)

The Sixth Edition is accompanied by a thoroughly revised and expanded *Study Guide with Programmed Units*, new *Test Item Files*, and a new, practical, and uncommonly complete *Instructor's Handbook* prepared by JOHN C. RUCH, Mills College.

Publication: January 1975

DORSEY

COMING IN JANUARY

BEHAVIOR MODIFICATION IN APPLIED SETTINGS

Alan E. Kazdin, *The Pennsylvania State University*

Focuses on the application of operant principles, implementation of behavior modification techniques, and the measurement and evaluation of program effectiveness. A major portion of the text elaborates positive reinforcement, punishment and negative reinforcement, and extinction. The book fills the hiatus between "how-to-do-it manuals" in behavior modification and extensive scholarly reviews which ignore much of applied research. Paperbound

SOCIAL BEHAVIORISM

Arthur Staats, *University of Hawaii*

Presents a liberated behavioristic view incorporating most of the virtues of recent advances in social learning. Staats utilizes a framework which provides broader coverage and better integration than other social behaviorisms. The text makes a number of specific new contributions including an advanced and pragmatic exposition of learning principles for the study of human behavior.

PERSONALITY: Strategies for the Study of Man, Revised Edition

Robert M. Liebert, *State University of New York at Stony Brook*, and Michael D. Spiegler, *University of Texas*

Acquaints the undergraduate majoring in psychology with important theoretical and research issues in the field. Completely updated with almost 100 new references and numerous contemporary research examples. Text Price: \$11.00

STUDIES IN PERSONNEL AND INDUSTRIAL PSYCHOLOGY, Third Edition

Edited by Edwin A. Fleishman, *American Institutes for Research*, Washington, D.C., and Alan R. Bass, *Wayne State University*

Includes recent articles which deal directly with socially relevant issues such as discrimination in employment, development of new techniques for personnel selection and appraisal, and new techniques for making work more meaningful and satisfying. Paperbound Text Price: \$8.50

Examination copies for adoption consideration available on request; please indicate course title and text presently used.

Standards for Educational and Psychological Tests

1974 revision.

Developed under a grant from the Russell Sage Foundation by a joint committee of members from the APA, the American Educational Research Association, and the National Council on Measurement in Education.

This current revision of **Standards** is directed equally toward establishing guidelines for test developers and test users. It proposes *essential*, *very desirable* and *desirable* considerations for the effective development and use of standardized tests. Additionally, each standard is accompanied by an exemplary or clarifying comment. 80 pp. \$3 to students and members of APA, AERA, NCME; \$5 to non-members.

Contents:

Introduction

Standards for Tests, Manuals and Reports

Standards for Reports of Research on Reliability and Validity

Standards for the Use of Tests

Please note that payment must accompany all orders amounting to \$15 or less except for those orders submitted on institutional purchase order forms.

SPLITTING A Case of Female Masculinity

Robert J. Stoller, M.D. This is the dramatic case history of a woman whose traumatic childhood caused her to split into several personalities. Her psychiatric symptoms included psychosis, multiple personalities, criminality, homosexuality and suicide attempts. These transcripts of her treatment sessions are interwoven with Dr. Stoller's piercing and controversial reflections on major psychiatric issues. "Typifies the best in modern psychiatric practice."—*Los Angeles Times*
DELTA paperback \$3.45

IN SEARCH OF COMMON GROUND

Conversations with Erik H. Erikson & Huey P. Newton

Introduced by Kai T. Erikson This extraordinary record of two meetings which took place between the noted psychological theorist and the founder of the Black Panther Party reveals how two men with vastly different ideological stances and life experiences came to grips with the differences between them. "Offers some badly needed clues to what the radicalism of the 1970's may come to be."—*The New York Times Book Review*

LAUREL paperback \$1.25

THE MASTER GAME

Beyond The Drug Experience

Robert S. De Ropp

Here is an exploration of the human psyche and detailed guide to the specific techniques of Creative Psychology, through which man can achieve the highest consciousness. Unlike other "games people play" the pursuit Dr. De Ropp describes is worth playing. "It is the kind of book that dawns and keeps dawning. Dr. De Ropp is an extraordinary guru."—Alastair Reid. "Will no doubt command the attention of thousands of probing Americans."—*The New York Times Book Review*.

DELTA paperback \$2.45; LAUREL paperback \$1.50

MAN'S AGGRESSION The Defense of the Self

Gregory Rochlin, M.D. The first book on the provocative new theory that human aggression arises from man's need to maintain his self-esteem. Dr. Rochlin explains that this characteristic of man is a device for neutralizing or transcending any threat or injury to self. Drawing from his clinical records, Freud, history, myth and literature, Dr. Rochlin shows the appearance of aggression in the infant before the first manifestations of sex and its continuance until death.

DELTA paperback \$2.95

THE RESURRECTION OF THE BODY

The Essential Writings of F. Matthias Alexander

Edited by Edward Maisel A stimulating introduction to the concepts and methods of a pioneer of mind-body unity and body reeducation to achieve physical well-being and improved emotional health. This collection of his works includes articles on the technique itself, on the way it works, and on its implications for social living. "This story of perceptiveness, of intelligence and of persistence... is one of the true epics of medical research and practice."—Professor Nicholaas Tinbergen, 1973 Nobel Prize Winner in Physiology/Medicine

DELTA paperback \$2.75

APA announces the reformatting of the **JOURNAL OF EXPERIMENTAL PSYCHOLOGY (JEP)**. Effective January 1975, the **JOURNAL** will be published as four independently edited and distributed sections. The broader editorial focus is intended to provide a mechanism for more integrative reports of general experimental research as well as the usual articles dealing with specialized areas of experimental psychology. The **Journal's** four sections are:

☐ **JEP: General.** Comprehensive and integrative reports of new research leading to a substantial advance in knowledge which are of interest to the entire community of experimental psychologists. Four issues published March, June, September, and December. \$6 to APA members only.

☐ **JEP: Human Learning and Memory.** Experimental studies on fundamental acquisition, retention, and transfer processes in human behavior. Six issues published January, March, May, July, September, and November. \$10 to APA members only.

☐ **JEP: Human Perception and Performance.** Experimental studies designed to foster understanding of information-processing operations and their relation to experience and performance. Four issues published February, May, August, and November. \$6 to APA members only.

☐ **JEP: Animal Behavior Processes.** Experimental studies concerning the basic mechanisms of perception, learning, motivation, and performance, especially as revealed in the behavior of infrahuman animals. **NOTE:** Animal experimental studies, formerly published in the *Journal of Comparative and Physiological Psychology*, have been reinstated as a major component of **JEP**. Four issues published January, April, July, and October. \$6 to APA members only.

■ **SPECIAL ORDERING INSTRUCTIONS:** APA members may subscribe singly, in self-selected combinations, or to all four sections for \$25 per year. Institutions and nonmembers must subscribe to all four sections at \$60 (Foreign \$61) per year. To order your subscription, please send your request accompanied by full payment or institutional purchase order to:

American Psychological Association
 **Subscription Department**
1200 17th Street, N.W.
Washington, D. C. 20036

Please note that all subscriptions must be prepaid except for those submitted on institutional purchase order forms. Subscriptions to **JEP** are on a calendar-year (January through December) basis only. Subscriptions entered during the year receive back issues for that year.

A MESSAGE FOR BOOK LOVERS:

We understand how many people feel about books. We also know microform doesn't have the aesthetic appeal of a bound volume. But microform *does* open up a world of written materials that you might otherwise never see! And that's the important thing.

To bring you these materials, Xerox University Microfilms has amassed a library of nearly a million volumes—some five centuries old, some as current as last month. Many are virtually impossible to obtain in original form, but readily available in microform—or (for book lovers) in library-bound versions.

Our ever expanding resources include extensive files of periodicals, newspapers, documents, and out-of-print books. We've also accumulated 300,000 doctoral dissertations, and add more than 30,000 new ones every year. And we've gathered special materials ranging from early English and American literature, to a collection of dissertations on the environment, to current issues of THE CONGRESSIONAL RECORD.

Our microform program enables your library to serve you better. How? Because even rare and hard-to-get titles are moderately priced in microform. So the money your library saves on film acquisitions can be used to purchase additional research materials. And, unlike paper, microforms are not apt to be missing pages or to disappear from the shelf.

So remember, when you don't have access to the original resource in paper, microform can often give you access to what it says. And after all, the printed word is worth far more than the paper it's printed on.

What kinds of resource materials do you need? Write and tell us your field of study. We'll let you know what we have that may be of interest to you.

The *American Psychologist* is the official publication of the American Psychological Association and, as such, contains archival documents as well as material submitted by authors. Articles should be timely and of broad general interest to psychologists of all scientific and professional persuasions. Manuscripts must adhere to the instructions on reference citations, preparation of tables and figures, manuscript format, etc., as described in the *Publication Manual of the American Psychological Association*. Manuscripts that do not conform to the style set forth in the *Manual* will be returned for revision. When in doubt about practices of the *Journal*, authors should examine a recent issue.

Articles under consideration or accepted by another periodical of general circulation are not acceptable. Also, articles accepted for publication by this *Journal* may not be reprinted elsewhere without APA permission. Comments should be submitted no later than two months from the date of the issue containing an article on which comment is made in order to ensure timeliness.

Submit manuscripts in triplicate, accompanied by a 100-120-word abstract, to Kenneth B. Little, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Statements contained in the *American Psychologist* are the personal views of the author and do not constitute APA policy unless so indicated. The American Psychological Association, founded in 1892 and incorporated in 1925, is the major psychological organization in the United States. The purpose of the APA is to advance psychology as a science, and as a means of promoting human welfare. It attempts to accomplish these objectives by holding annual meetings, publishing psychological journals, and working toward improved standards for psychological training and service.

In addition to the *American Psychologist*, the Association publishes 13 other journals: *Contemporary Psychology*, *Developmental Psychology*, *Journal of Abnormal Psychology*, *Journal of Applied Psychology*, *Journal of Comparative and Physiological Psychology*, *Journal of Consulting and Clinical Psychology*, *Journal of Counseling Psychology*, *Journal of Educational Psychology*, *Journal of Experimental Psychology*, *Journal of Personality and Social Psychology*, *Professional Psychology*, *Psychological Bulletin*, and *Psychological Review*. The APA also publishes *Psychological Abstracts*, the *APA Monitor*, a monthly *Employment Bulletin*, the *Biographical Directory*, the *Convention Program*, and the *Catalog of Selected Documents in Psychology*.

Behavior Theory and the Models of Man

ALBERT BANDURA *Stanford University*¹

The views about the nature of man conveyed by behavior theory require critical examination on conceptual and social grounds. What we believe man to be affects which aspects of human functioning we study most thoroughly and which we disregard. Premises thus delimit research and are, in turn, shaped by it. As knowledge gained through study is put into practice, the images of man on which social technologies rest have even vaster implications. This is nowhere better illustrated than in growing public concern over manipulation and control by psychological methods. Some of these fears arise from expectations that improved means of influence will inevitably be misused. Other apprehensions are aroused by exaggerated claims of psychological power couched in the language of manipulation and authoritarian control. But most fears stem from views of behaviorism, articulated by popular writers and by theorists themselves, that are disputed by the empirical facts of human behavior.

In the minds of the general public, and of many within our own discipline, behavior theory is equated with "conditioning." Over the years, the terms *behaviorism* and *conditioning* have come to be associated with odious imagery, including salivating dogs, puppetry, and animalistic manipulation. As a result, those who wish to disparage ideas or practices they hold in disfavor need only to label them as behavioristic or as Pavlovian precursors of a totalitarian state.

Contrary to popular belief, the fabled reflexive conditioning in humans is largely a myth. *Conditioning* is simply a descriptive term for learning through paired experiences, not an explanation of how the changes come about. Originally, conditioning was assumed to occur automatically. On

closer examination it turned out to be cognitively mediated. People do not learn despite repetitive paired experiences unless they recognize that events are correlated (Dawson & Furedy, 1974; Grings, 1973). So-called conditioned reactions are largely self-activated on the basis of learned expectations rather than automatically evoked. The critical factor, therefore, is not that events occur together in time, but that people learn to predict them and to summon up appropriate anticipatory reactions.

The capacity to learn from correlated experiences reflects sensitivity, but because Pavlov first demonstrated the phenomenon with a dog, it has come to be regarded as a base animalistic process. Had he chosen to study physiological hyperactivity in humans to cues associated with stress, or the development of empathetic reactions to expressions of suffering, conditioning would have been treated in a more enlightened way. To expect people to remain unaffected by events that are frightening, humiliating, disgusting, sad, or pleasurable is to require that they be less than human. Although negative effects such as fears and dislikes can arise from paired experiences of a direct or vicarious sort, so do some of the ennobling qualities of man. The pejorative accounts of learning principles, which appear with regularity in professional and lay publications, degrade both the science of psychology and the audiences that the offensive rhetoric is designed to sway.

It is well documented that behavior is influenced by its consequences much of the time. The image of man that this principle connotes depends on the types of consequences that are acknowledged and on an understanding of how they operate. In theories that recognize only the role of proximate external consequences and contend they shape behavior automatically, people appear as mechanical pawns of environmental forces. But external consequences, influential as they often are, are not the sole determinants of human behavior, nor do they operate automatically.

¹Presidential Address presented at the meeting of the American Psychological Association, New Orleans, August 1974.

Response consequences serve several functions. First, they impart information. By observing the effects of their actions individuals eventually discern which behaviors are appropriate in which settings. The acquired information then serves as a guide for action. Contrary to the mechanistic metaphors, outcomes change behavior in humans through the intervening influence of thought.

Consequences motivate, through their incentive value, as well as inform. By representing foreseeable outcomes symbolically, future consequences can be converted into current motivators of behavior. Many of the things we do are designed to gain anticipated benefits and to avert future trouble. Our choices of action are largely under anticipatory control. The widely accepted dictum that man is ruled by response consequences thus fares better for anticipated than for actual consequences. Consider behavior on a fixed-ratio schedule (say, 50:1) in which only every fiftieth response is reinforced. Since 96% of the outcomes are extinctive and only 4% are reinforcing, behavior is maintained despite its dissuading consequences. As people are exposed to variations in frequency and predictability of reinforcement, they behave on the basis of the outcomes they expect to prevail on future occasions. When belief differs from actuality, which is not uncommon, behavior is weakly controlled by its actual consequences until repeated experience instills realistic expectations (Bandura, 1971b; Kaufman, Baron, & Kopp, 1966).

Had humans been ruled solely by instant consequences, they would have long become museum pieces among the extinct species. Not that our future is unquestionably secure. The immediate rewards of consumptive life-styles vigorously promoted for short-term profit jeopardize man's long-term chances of survival. But immediate consequences, unless unusually powerful, do not necessarily outweigh deferred ones (Mischel, 1974). Our descendants shall continue to have a future only because those who foresee the aversive long-term consequences of current practices mobilize public support for contingencies that favor survival behavior. Hazardous pesticides, for example, are usually banned before populations suffer maladies from toxic residues. The information-processing capacities with which humans are endowed provide the basis for insightful behavior. Their capacity to bring remote consequences to

bear on current behavior by anticipatory thought supports foresightful action.

Explanations of reinforcement originally assumed that consequences increase behavior without conscious involvement. The still prevalent notion that reinforcers can operate insidiously arouses fears that improved techniques of reinforcement will enable authorities to manipulate people without their knowledge or consent. Although the empirical issue is not yet completely resolved, there is little evidence that rewards function as automatic strengtheners of human conduct. Behavior is not much affected by its consequences without awareness of what is being reinforced (Bandura, 1969; Dulany, 1968). After individuals discern the instrumental relation between action and outcome, contingent rewards may produce accommodating or oppositional behavior depending on how they value the incentives, the influencers and the behavior itself, and how others respond. Thus reinforcement, as it has become better understood, has changed from a mechanical strengthener of conduct to an informative and motivating influence.

People do not function in isolation. As social beings, they observe the conduct of others and the occasions on which it is rewarded, disregarded, or punished. They can therefore profit from observed consequences as well as from their own direct experiences (Bandura, 1971c). Acknowledgment of vicarious reinforcement introduces another human dimension—namely, evaluative capacities—into the operation of reinforcement influences. People weigh consequences to themselves against those accruing to others for similar behavior. The same outcome can thus become a reward or a punishment depending upon the referents used for social comparison.

Human conduct is better explained by the relational influence of observed and direct consequences than by either factor alone. However, behavior is not fully predictable from a relational coefficient because social justifications alter the impact of outcome disparities. Inequitable reinforcement is willingly accepted when people are graded by custom into social ranks and rewarded according to position rather than by performance. Arbitrary inequities are also likely to be tolerated if the underrewarded are led to believe they possess attributes that make them less deserving of equal treatment. Persuasively justified inequities have more detrimental personal effects than acknowledged unfairness because they foster self-de-

valuation in the maltreated. Negative reactions to inequitable reinforcement, which is acknowledged to be unwarranted, can likewise be diminished by temporizing. If people are led to expect that unfair treatment will be corrected within the foreseeable future, it becomes less aversive to them.

Theories that explain human behavior as the product of external rewards and punishments present a truncated image of man because people partly regulate their actions by self-produced consequences (Bandura, 1971c; Thoresen & Mahoney, 1973). Example and precept impart standards of conduct that serve as the basis for self-reinforcing reactions. The development of self-reactive functions gives humans a capacity for self-direction. They do things that give rise to self-satisfaction and self-worth, and they refrain from behaving in ways that evoke self-punishment.

After self-reinforcing functions are acquired, a given act produces two sets of consequences: self-evaluative reactions and external outcomes. Personal and external sources of reinforcement may operate as supplementary or as opposing influences on behavior. Thus, for example, individuals commonly experience conflicts when rewarded for conduct they personally devalue. When self-condemning consequences outweigh rewarding inducements, external influences are relatively ineffective. On the other hand, if certain courses of action produce stronger rewards than self-censure, the result is cheerless compliance. Losses in self-respect for devalued conduct can be abated, however, by self-exonerating justifications. I shall return to this issue shortly.

Another type of conflict between external and self-produced consequences arises when individuals are punished for behavior they regard highly. Principled dissenters and nonconformists often find themselves in this predicament. Personally valued conduct is expressed provided its costs are not too high. Should the threatened consequences be severe, one inhibits self-praiseworthy acts under high risk of penalty but readily performs them when the chances of punishment are reduced. There are individuals, however, whose sense of self-worth is so strongly invested in certain convictions that they will submit to prolonged maltreatment rather than accede to what they regard as unjust or immoral.

External consequences exert greatest influence on behavior when they are compatible with those that are self-produced. These conditions obtain when

rewardable acts are a source of self-pride and punishable ones are self-censured. To enhance compatibility between personal and social influences, people select associates who share similar standards of conduct and thus ensure social support for their own system of self-reinforcement.

Individualistic theories of moral action assume that internalization of behavioral standards creates a permanent control mechanism within the person. Restraints of conscience thereafter operate as enduring controls over reprehensible conduct. The testimony of human behavior, however, contradicts this view. Much human maltreatment and suffering are, in fact, inflicted by otherwise decent moral people. And some of the most striking changes in moral conduct, as evidenced, for example, in political and military violence, are achieved without altering personality structures or moral standards. Personal control is clearly more complex and flexible than the theorizing implies.

Although self-reinforcing influences serve as regulators of conduct, they can be dissociated from censurable deeds by self-exonerating practices (Bandura, 1973). One device is to make inhumane behavior personally and socially acceptable by defining it in terms of high moral principle. People do not act in ways they ordinarily consider evil or destructive until such activities are construed as serving moral purposes. Over the years, much cruelty has been perpetrated in the name of religious principles, righteous ideologies, and regulatory sanctions. In the transactions of everyday life, euphemistic labeling serves as a handy linguistic device for masking reprehensible activities or according them a respectable status. Self-deplored conduct can also be made benign by contrasting it with more flagrant inhumanities. Moral justifications and palliative comparisons are especially effective because they not only eliminate self-generated deterrents but engage self-reward in the service of reprehensible conduct. What was morally unacceptable becomes a source of self-pride.

A common dissociative practice is to obscure or distort the relationship between one's actions and the effects they cause. People will perform behavior they normally repudiate if a legitimate authority sanctions it and acknowledges responsibility for its consequences. By displacing responsibility elsewhere, participants do not hold themselves accountable for what they do and are thus spared self-prohibiting reactions. Exemption

from self-censure can be facilitated additionally by diffusing responsibility for culpable behavior. Through division of labor, division of decision making, and collective action, people can contribute to detrimental practices without feeling personal responsibility or self-disapproval.

Attribution of blame to the victim is still another exonerative expedient. Victims are faulted for bringing maltreatment on themselves, or extraordinary circumstances are invoked as justifications for questionable conduct. One need not engage in self-reproof for committing acts prescribed by circumstances. A further means of weakening self-punishment is to dehumanize the victim. Inflicting harm upon people who are regarded as subhuman or debased is less likely to arouse self-reproof than if they are looked upon as human beings with sensitivities.

There are other self-disinhibiting maneuvers that operate by misrepresenting the consequences of actions. As long as detrimental effects are ignored or minimized, there is little reason for self-censure. If consequences are not easily distortable, distress over conduct that conflicts with self-evaluative standards can be reduced by selectively remembering the benefits and forgetting the harm of one's acts.

Given the variety of self-disinhibiting devices, a society cannot rely on control by conscience to ensure moral and ethical conduct. Though personal control ordinarily serves as a self-directive force, it can be nullified by social sanctions conducive to destructiveness. Indoctrination and social justifications give meaning to events and create anticipations that determine one's actions. Control through information, which is rooted in cognitive processes, is more pervasive and powerful than conditioning through contiguity of events. Cultivation of humaneness therefore requires, in addition to benevolent personal codes, safeguards built into social systems that counteract detrimental sanctioning practices and uphold compassionate behavior.

A conceptual orientation not only prescribes what facets of man will be studied in depth but also how one goes about changing human behavior. Early applications of reinforcement principles, for example, were guided by the then prevalent belief that consequences alter behavior automatically and unconsciously. Since the process supposedly operated mechanically, the reinforcers had to occur instantly to be effective. Participants in change programs were, therefore, uninformed about why

they were being reinforced, and, in an effort to ensure immediacy of effects, reinforcers were presented intrusively as soon as the requisite responses were emitted. The net effect was a tedious shaping process that produced, at best, mediocre results in an ethically questionable manner. In many public and professional circles, reinforcement still connotes furtive control even though reinforcement theory and practices have progressed well beyond this level.

Realization that reinforcement is an unarticulated way of designating appropriate conduct prompted the use of cognitive factors in the modification of behavior. Not surprisingly, people change more rapidly if told what behaviors are rewardable and punishable than if they have to discover it from observing the consequences of their actions. Competencies that are not already within their repertoires can be developed with greater ease through the aid of instruction and modeling than by relying solely on the successes and failures of unguided performance.

As further research revealed that reinforcers function as motivators, consequences were recognized as sources of motivation that depend heavily for their effectiveness upon the incentive preferences of those undergoing change. Hence, people do not indiscriminately absorb the influences that impinge upon them. Outcomes resulting from actions need not necessarily occur instantly. Humans can cognitively bridge delays between behavior and subsequent reinforcers without impairing the efficacy of incentive operations.

At this second evolutionary stage, reinforcement practices changed from unilateral control to social contracting. Positive arrangements affirm that if individuals do certain things they are entitled to certain rewards and privileges. In the case of negative sanctions, reprehensible conduct carries punishment costs. The process is portrayed in reinforcement terms, but the practice is that of social exchange. Most social interactions are, of course, governed by conditional agreements, though they usually are not couched in the language of reinforcement. Describing them differently does not change their nature, however.

Contingencies vary in the human qualities they embody and in the voice individuals have in decisions concerning the social arrangements that affect their lives. Reflecting the salient values of our society, reinforcement practices have traditionally favored utilitarian forms of behavior. But

conditions are changing. With growing reservations about materialistic life-styles, reinforcement practices are being increasingly used to cultivate personal potentialities and humanistic qualities. These emerging changes in value commitments will probably accelerate as people devote fewer hours to working for income and have more leisure time for self-development.

Another change of some consequence is the renewed concern for individual rights. People are seeking a collaborative role in the development of societal contingencies that affect the course and quality of their lives. As part of this social trend, even the actions taken in the name of psychotherapy are being examined for their ethics and social purposes. These concerns have provided the impetus for prescripts to ensure that reinforcement techniques are used in the service of human betterment rather than as instruments of social control.

A closely related issue is the relative attention devoted to changing individuals or to altering the institutions of society to enrich life. If psychologists are to have a significant impact on common problems of life, they must apply their corrective measures to detrimental societal practices rather than limit themselves to treating the casualties of these practices. This, of course, is easier said than done. Practitioners, whatever their specialty, are reinforced more powerfully for using their knowledge and skills in the service of existing operations than for changing them. Socially oriented efforts are hard to sustain under inadequate reinforcement supports.

The methods of change discussed thus far draw heavily upon external consequences of action. Evidence that people can exercise some control over their own behavior provided the impetus for further changes in reinforcement practices. Interest began to shift from managing conduct to developing skills in self-regulation. In the latter approach, control is vested to a large extent in the hands of individuals themselves: They arrange the environmental inducements for desired behavior; they evaluate their own performances; and they serve as their own reinforcing agents (Goldfried & Merbaum, 1973; Mahoney & Thoresen, 1974). To be sure, the self-reinforcing functions are created and occasionally supported by external influences. Having external origins, however, does not refute the fact that, once established, self-influence partly determines what actions one performs. Citing historical determinants of a generalizable function

cannot substitute for contemporaneous influences arising through exercise of that function.

The recognition of self-directing capacities represents a substantial departure from exclusive reliance upon environmental control. But the emerging self-influence practices are still closely rooted in physical transactions—the self-administered consequences are, for the most part, material. Eventually changes in form, as well as source, of reinforcement will appear as the insufficiency of material outcomes is acknowledged. Most people value their self-respect above commodities. They rely extensively on their own self-demands and self-approval as guides for conduct. To ignore the influential role of covert self-reinforcement in the regulation of behavior is to disavow a uniquely human capacity of man.

Proponents who recognize only external consequences restrict their research and practice to such influences and thus generate evidence that reinforces their conceptions. Those who acknowledge personal influences as well tend to select methods that reveal and promote self-directing capabilities in man. The view of man embodied in behavioral technologies is therefore more than a philosophical issue. It affects which human potentialities will be cultivated and which will be underdeveloped.

The preceding remarks addressed the need to broaden the scope of research into the reinforcement processes regulating human behavior. Much the same might be said for the ways in which human learning is conceptualized and investigated. Our theories have been incredibly slow in acknowledging that man can learn by observation as well as by direct experience. This is another example of how steadfast adherence to orthodox paradigms makes it difficult to transcend the confines of conceptual commitment. Having renounced cognitive determinants, early proponents of behaviorism advanced the doctrine that learning can occur only by performing responses and experiencing their effects. This legacy is still very much with us. The rudimentary form of learning based on direct experience has been exhaustively studied, whereas the more pervasive and powerful mode of learning by observation is largely ignored. A shift of emphasis is needed.

The capacity to represent modeled activities symbolically enables man to acquire new patterns of behavior observationally without reinforced enactment. From observing others, one forms an idea of how certain behavior is performed, and on

later occasions the coded information serves as a guide for action. Indeed, research conducted within the framework of social learning theory shows that virtually all learning phenomena resulting from direct experience can occur on a vicarious basis by observing other people's behavior and its consequences for them (Bandura, 1969). The abbreviation of the acquisition process through observational learning is, of course, vital for both development and survival. Modeling reduces the burden of time-consuming performance of inappropriate responses. Since errors can produce costly, if not fatal, consequences, the prospects of survival would be slim indeed if people had to rely solely on the effects of their actions to inform them about what to do.

In many instances the behavior being modeled must be learned in essentially the same form. Driving automobiles, skiing, and performing surgery, for example, permit little, if any, departure from essential practices. In addition to transmitting particular response patterns, however, modeling influences can create generative and innovative behavior. In the latter process, observers abstract common features from seemingly diverse responses and formulate generative rules of behavior that enable them to go beyond what they have seen or heard. By synthesizing features of different models into new amalgams, observers can achieve through modeling novel styles of thought and conduct. Once initiated, experiences with the new forms create further evolutionary changes. A partial departure from tradition eventually becomes a new direction.

Some of the limitations commonly ascribed to behavior theory are based on the mistaken belief that modeling can produce at best mimicry of specific acts. This view is disputed by growing evidence that abstract modeling is a highly effective means of inducing rule-governed cognitive behavior (Bandura, 1971a; Zimmerman & Rosenthal, 1974). On the basis of observationally derived rules, people alter their judgmental orientations, conceptual schemes, linguistic styles, information-processing strategies, as well as other forms of cognitive functioning. Nevertheless, faulty evaluations continue to be mistaken for weaknesses inherent in theory.

Observational learning has recently come to be accepted more widely, but some theorists are willing to grant it full scientific respectability only if it is reduced to performance terms. As a result,

enactment paradigms are used which are rooted in the traditional assumption that responses must be performed before they can be learned. Instant reproduction of modeled responses is favored, thereby minimizing dependence upon cognitive functions which play an especially influential role when retention over time is required. The issue of whether reinforcement enhances modeling is pursued to the neglect of the more interesting question of whether one can keep people from learning what they have seen.

When learning is investigated through observational paradigms, a broader range of determinants and intervening mechanisms gains prominence. Learning by observation is governed by four component processes: (a) attentional functions regulate sensory input and perception of modeled actions; (b) through coding and symbolic rehearsal, transitory experiences are transformed for memory representation into enduring performance guides; (c) motor reproduction processes govern the integration of constituent acts into new response patterns; and (d) incentive or motivational processes determine whether observationally acquired responses will be performed. Studied from this perspective, observational learning emerges as an actively judgmental and constructive, rather than a mechanical copying, process.

Because observational learning entails several subfunctions that evolve with maturation and experience, it obviously depends upon prior development. Differences in theoretical perspectives prescribe different methodologies for studying how the capacity for observational learning itself is acquired. When modeling is conceptualized in terms of formation of stimulus-response linkages, efforts are aimed at increasing the probability of imitative responses through reinforcement. Modeling can be increased by rewarding matching behavior, but such demonstrations are not of much help in identifying what exactly is being acquired during the process, or in explaining imitation failures under favorable conditions of reinforcement. From a social learning view, the capability for observational learning is developed by acquiring skill in discriminative observation, in memory encoding, in coordinating ideomotor and sensorimotor systems, and in judging probable consequences for matching behavior. Understanding how people learn to imitate becomes a matter of understanding how the requisite subfunctions develop and operate. Capacity for observational learning is restricted by

deficits, and expanded by improvements, in its component functions.

Over the years, proponents of the more radical forms of behaviorism not only disclaimed interest in mentation but also marshaled numerous reasons why cognitive events are inadmissible in causal analyses. It was, and still is, argued that cognitions are inaccessible except through untrustworthy self-reports, they are inferences from effects, they are epiphenomenal, or they are simply fictional. Advances in experimental analysis of behavior, it was claimed, would eventually show them to be unnecessary. Empirical evidence, however, has shown the opposite to be true. A large body of research now exists in which cognition is activated instructionally with impressive results. People learn and retain much better by using cognitive aids that they generate than by repetitive reinforced performance (Anderson & Bower, 1973; Bandura, 1971a). With growing evidence that cognition has causal influence in behavior, the arguments against cognitive determinants are losing their force.

These recent developments have shifted emphasis from the study of response learning to analyses of memory and cognition. From this effort we have gained a better understanding of the mechanisms whereby information is acquired, stored, and retrieved. There is more to learning, however, than the acquisition and retention of information. Behavioristic theories addressed themselves to performance but deemphasized internal determinants, whereas the cognitive approaches remain immersed in thought but divorced from conduct. In a complete account of human behavior, internal processes must eventually be tied to action. Hence, explanations of how information eventuates in skilled performance must additionally be concerned with the organization and regulation of behavior. Social learning includes within its framework both the processes internal to the organism as well as performance-related determinants.

Speculations about man's nature inevitably raise the fundamental issues of determinism and human freedom. In examining these questions it is essential to distinguish between the metaphysical and the social aspects of freedom. Many of the heated disputes on this topic arise as much, if not more, from confusion over the dimensions of freedom being discussed as from disagreements over the doctrine of determinism.

Let us first consider freedom in the social sense. Whether freedom is an illusion, as some writers

maintain, or a social reality of considerable importance depends upon the meaning given to it. Within the social learning framework, freedom is defined in terms of the number of options available to people and the right to exercise them. The more behavioral alternatives and social prerogatives people have, the greater is their freedom of action.

Personal freedom can be limited in many different ways. Behavioral deficits restrict possible choices and otherwise curtail opportunities to realize one's preferences. Freedom can therefore be expanded by cultivating competencies. Self-restraints arising from unwarranted fears and stringent self-censure restrict the effective range of activities that individuals can engage in or even contemplate. Here freedom is restored by eliminating dysfunctional self-restraints.

In maximizing freedom a society must place some limits on conduct because complete license for any individual is likely to encroach on the freedom of others. Societal prohibitions against behavior that is socially injurious create additional curbs on conduct. Conflicts often arise over behavioral restrictions when many members of society question conventional customs and when legal sanctions are used more to enforce a particular brand of morality than to prohibit socially detrimental conduct.

The issue of whether individuals should be allowed to engage in activities that are self-injurious but not detrimental to society has been debated vigorously over the years. Prohibitionists argue that it is difficult for a person, other than a recluse, to impair himself without inflicting secondary harm on others. Should self-injury produce incapacities, society usually ends up bearing the treatment and subsistence costs. Libertarians do not find such arguments sufficiently convincing to justify a specific prohibition because some of the self-injurious activities that society approves may be as bad or worse than those it outlaws. Normative changes over time regarding private conduct tend to favor an individualistic ethic. Consequently, many activities that were formerly prohibited by law have been exempted from legal sanctions.

Some groups have their freedom curtailed by socially condoned discrimination. Here, the alternatives available to a person are limited by skin color, sex, religion, ethnic background, or social class, regardless of capabilities. When self-termination is prejudicially restricted, those who are subordinated remove inequities by altering

practices that compromise or temporize the professed values of society.

Freedom deals with rights as well as options and behavioral restraints. Man's struggle for freedom is principally aimed at structuring societal contingencies so that certain forms of behavior are exempted from aversive control. After protective laws are built into the system, there are certain things that a society may not do to an individual, however much it might like to. Legal prohibitions on societal control create freedoms that are realities, not simply feelings or states of mind. Societies differ in their institutions of freedom and in the number and types of behaviors that are officially exempted from punitive control. Social systems that protect journalists from punitive control, for example, are freer than those that allow authoritative power to be used to silence critics or their vehicles of expression. Societies that possess an independent judiciary ensure greater social freedom than those that do not.

In philosophical discourses, freedom is often considered antithetical to determinism. When defined in terms of options and rights, there is no incompatibility of freedom and determinism. From this perspective, freedom is not conceived negatively as the absence of influences or simply the lack of external constraints. Rather, it is defined positively in terms of the skills at one's command and the exercise of self-influence upon which choice of action depends.

Psychological analyses of freedom eventually lead to discourses on the metaphysics of determinism. Are people partial determiners of their own behavior, or are they ruled exclusively by forces beyond their control? The long-standing debate over this issue has been enlivened by Skinner's (1971) contention that, apart from genetic contributions, human behavior is controlled solely by environmental contingencies, for example, "A person does not act upon the world, the world acts upon him" (p. 211). A major problem with this type of analysis is that it depicts the environment as an autonomous force that automatically shapes and controls behavior. Environments have causes as do behaviors. For the most part, the environment is only a potentiality until actualized and fashioned by appropriate actions. Books do not influence people unless someone writes them and others select and read them. Rewards and punishments remain in abeyance until prompted by appropriate performances.

It is true that behavior is regulated by its con-

tingencies, but the contingencies are partly of a person's own making. By their actions, people play an active role in producing the reinforcing contingencies that impinge upon them. Thus, behavior partly creates the environment, and the environment influences the behavior in a reciprocal fashion. To the oft-repeated dictum, change contingencies and you change behavior, should be added the reciprocal side, change behavior and you change the contingencies.

The image of man's efficacy that emerges from psychological research depends upon which aspect of the reciprocal control system one selects for analysis. In the paradigm favoring environmental control, investigators analyze how environmental contingencies change behavior [$B = f(E)$]. The personal control paradigm, on the other hand, examines how behavior determines the environment [$E = f(B)$]. Behavior is the effect in the former case, and the cause in the latter. Although the reciprocal sources of influence are separable for experimental purposes, in everyday life two-way control operates concurrently. In ongoing interchanges, one and the same event can thus be a stimulus, a response, or an environmental reinforcer depending upon the place in the sequence at which the analysis arbitrarily begins.

A survey of the literature on reinforcement confirms the extent to which we have become captives of a one-sided paradigm to map a bidirectional process. Environmental control is overstudied, whereas personal control has been relatively neglected. To cite but one example, there exist countless demonstrations of how behavior varies under different schedules of reinforcement, but one looks in vain for studies of how people, either individually or by collective action, succeed in fashioning reinforcement schedules to their own liking. The dearth of research on personal control is not because people exert no influence on their environment or because such efforts are without effect. Quite the contrary. Behavior is one of the more influential determinants of future contingencies. As analyses of sequential interchanges reveal, aggressive individuals actualize through their conduct a hostile environment, whereas those who display friendly responsiveness produce an amicable social milieu within the same setting (Rausch, 1965). We are all acquainted with problem-prone individuals who, through their aversive conduct, predictably breed negative social climates wherever they go.

It should be noted that some of the doctrines

ascribing preeminent control to the environment are ultimately qualified by acknowledgment that man can exercise some measure of countercontrol (Skinner, 1971). The notion of reciprocal interaction, however, goes considerably beyond the concept of countercontrol. Countercontrol portrays the environment as an instigating force to which individuals react. As we have already seen, people activate and create environments as well as rebut them.

People may be considered partially free insofar as they can influence future conditions by managing their own behavior. Granted that selection of particular courses of action from available alternatives is itself determined, individuals can nevertheless exert some control over the factors that govern their choices. In philosophical analyses all events can be submitted to an infinite regression of causes. Such discussions usually emphasize how man's actions are determined by prior conditions but neglect the reciprocal part of the process showing that the conditions themselves are partly determined by man's prior actions. Applications of self-control practices demonstrate that people are able to regulate their own behavior in preferred directions by arranging environmental conditions most likely to elicit it and administering self-reinforcing consequences to sustain it. They may be told how to do it and initially be given some external support for their efforts, but self-produced influences contribute significantly to future goal attainment.

To contend, as environmental determinists often do, that people are controlled by external forces and then to advocate that they redesign their society by applying behavioral technology undermines the basic premise of the argument. If humans were in fact incapable of influencing their own actions, they could describe and predict environmental events but hardly exercise any intentional control over them. When it comes to advocacy of social change, however, thoroughgoing environmental determinists become ardent exponents of man's power to transform environments in pursuit of a better life.

In backward causal analyses, conditions are usually portrayed as ruling man, whereas forward deterministic analyses of goal setting and attainment reveal how people can shape conditions for their purposes. Some are better at it than others. The greater their foresight, proficiency, and self-influence, all of which are acquirable skills, the greater the progress toward their goals. Because of

the capacity for reciprocal influence, people are at least partial architects of their own destinies. It is not determinism that is in dispute, but whether it is treated as a one-way or a two-way control process. Considering the interdependence of behavior and environmental conditions, determinism does not imply the fatalistic view that man is but a pawn of external influences.

Psychological perspectives on determinism, like other aspects of theorizing, influence the nature and scope of social practice. Environmental determinists are apt to use their methods primarily in the service of institutionally prescribed patterns of behavior. Personal determinists are more inclined to cultivate self-directing potentialities in man. The latter behavioral approach and humanism have much in common. Behavioral theorists, however, recognize that "self-actualization" is by no means confined to human virtues. People have numerous potentialities that can be actualized for good or ill. Over the years, man has suffered considerably at the hands of self-actualized tyrants. A self-centered ethic of self-realization must therefore be tempered by concern for the social consequences of one's conduct. Behaviorists generally emphasize environmental sources of control, whereas humanists tend to restrict their interest to personal control. Social learning encompasses both aspects of the bidirectional influence process.

When the environment is regarded as an autonomous rather than as an influenceable determinant of behavior, valuation of dignifying human qualities and accomplishments is diminished. If inventiveness emanates from external circumstances, it is environments that should be credited for people's achievements and chastised for their failings or inhumanities. Contrary to the unilateral view, human accomplishments result from reciprocal interaction of external circumstances with a host of personal determinants including endowed potentialities, acquired competencies, reflective thought, and a high level of self-initiative.

Musical composers, for example, help to shape tastes by their creative efforts, and the public in turn supports their performances until advocates of new styles generate new public preferences. Each succeeding form of artistry results from a similar two-way influence process for which neither artisans nor circumstances deserve sole credit.

Superior accomplishments, whatever the field, require considerable self-disciplined application. After individuals adopt evaluative standards, they expend large amounts of time, on their own,

improving their performances to the point of self-satisfaction. At this level of functioning, persistence in an endeavor is extensively under self-reinforcement control. Skills are perfected as much, or more, to please oneself as to please the public.

Without self-generated influences most innovative efforts would be difficult to sustain. This is because the unconventional is initially resisted and gradually accepted only as it proves functionally valuable or wins prestigious advocates. As a result, the early efforts of innovators bring rebuffs rather than rewards or recognition. In the history of creative endeavors, it is not uncommon for artists or composers to be scorned when they depart markedly from convention. Some gain recognition later in their careers. Others are sufficiently convinced of the worth of their work that they labor indefatigably even though their productions are negatively received during their lifetimes. Ideological and, to a lesser extent, technological advances follow similar courses. Most innovative endeavors receive occasional social support in early phases, but environmental conditions alone are not especially conducive to unconventional developments.

The operation of reciprocal influence also has bearing on the public concern that advances in psychological knowledge will produce an increase in human manipulation and control. A common response to such apprehensions is that all behavior is inevitably controlled. Social influence, therefore, is not a question of imposing controls where none existed before. This type of argument is valid in the sense that every act has a cause. But it is not the principle of causality that worries people. At the societal level, their misgivings center on the distribution of controlling power, the means and purposes for which it is used, and the availability of mechanisms for exercising reciprocal control over institutional practices. At the individual level, they are uneasy about the implications of psychotechnology in programming human relations.

Possible remedies for exploitative use of psychological techniques are usually discussed in terms of individual safeguards. Increased knowledge about modes of influence is prescribed as the best defense against manipulation. When people are informed about how behavior can be controlled, they tend to resist evident attempts at influence, thus making manipulation more difficult. Awareness alone, however, is a weak countervalance.

Exploitation was successfully thwarted long before there existed a discipline of psychology to

formulate principles and practices of behavior change. The most reliable source of opposition to manipulative control resides in the reciprocal consequences of human interactions. People resist being taken advantage of, and will continue to do so in the future, because compliant behavior produces unfavorable consequences for them. Sophisticated efforts at influence in no way reduce the aversiveness of yielding that is personally disadvantageous. Because of reciprocal consequences, no one is able to manipulate others at will, and everyone experiences some feeling of powerlessness in getting what they want. This is true at all levels of functioning, individual and collective. Parents cannot get their children to follow all their wishes, while children feel constrained by their parents from doing what they desire. At universities, the administrators, faculty, students, and alumni all feel that the other constituencies are unduly influential in promoting their self-interests but that one's own group is granted insufficient power to alter the institutional practices. In the political arena, Congress feels that the executive branch possesses excessive power, and conversely the executive branch feels thwarted in implementing its policies by congressional counteraction.

If protection against exploitation relied solely upon individual safeguards, people would be continually subjected to coercive pressures. Accordingly, they create institutional sanctions which set limits on the control of human behavior. The integrity of individuals is largely secured by societal safeguards that place constraints on improper means and foster reciprocity through balancing of interests.

Because individuals are conversant with psychological techniques does not grant them license to impose them on others. Industrialists, for example, know full well that productivity is higher when payment is made for amount of work completed rather than for length of time at work. Nevertheless, they cannot use the reinforcement system most advantageous to them. When industrialists commanded exclusive power, they paid workers at a piece-rate basis and hired and fired them at will. Reductions in power disparity between employers and employees resulted in a gradual weakening of performance requirements. As labor gained economic coercive strength through collective action, it was able to negotiate guaranteed wages on a daily, weekly, monthly, and eventually on an annual basis. At periodic intervals new contractual contingencies are adopted that are mutually ac-

ceptable. In the course of time, as better means of joint action are developed, other constituents will use their influence to modify arrangements that benefit certain segments of labor and industry but adversely affect the quality of life for other sectors of society.

As the previous example illustrates, improved knowledge of how to influence behavior does not necessarily raise the level of social control. If anything, the recent years have witnessed a diffusion of power, creating increased opportunities for reciprocal influence. This has enabled people to challenge social inequities, to effect changes in institutional practices, to counteract infringements on their rights, and to extend grievance procedures and due process of law to activities in social contexts that hitherto operated under unilateral control. The fact that more people wield power does not in and of itself ensure a humane society. In the final analysis, the important consideration is the purposes that power serves, however it might be distributed. Nor does knowledgeability about means of influence necessarily produce mechanical responsiveness in personal relations. Whatever their orientations, people model, expound, and reinforce what they value. Behavior arising out of purpose and commitment is no less genuine than improvised action.

The cliché of 1984, and its more recent kin, diverts public attention from regulative influences that pose continual threats to human welfare. Most societies have instituted reciprocal systems that are protected by legal and social codes to prevent imperious control of human behavior. Although abuses of institutional power arise from time to time, it is not totalitarian rule that constitutes the impending peril. The hazards lie more in the intentional pursuit of personal gain, whether material or otherwise, than in control by coercion. Detrimental social practices arise and resist change, even within an open society, when many people benefit from them. To take a prevalent example, inequitable treatment of disadvantaged groups for private gain enjoys public support without requiring despotic rule.

Man, of course, has more to contend with than inhumanities toward one another. When the aversive consequences of otherwise rewarding life-styles are delayed and imperceptibly cumulative, people become willful agents of their own self-destruction. Thus, if enough people benefit from activities that progressively degrade their environment, then, barring contravening influences, they will eventually

destroy their environment. Although individuals contribute differentially to the problem, the harmful consequences are borne by all. With growing populations and spread of lavish life-styles taxing finite resources, people will have to learn to cope with new realities of human existence.

Psychology cannot tell people how they ought to live their lives. It can, however, provide them with the means for effecting personal and social change. And it can aid them in making value choices by assessing the consequences of alternative life-styles and institutional arrangements. As a science concerned about the social consequences of its applications, psychology must also fulfill a broader obligation to society by bringing influence to bear on public policies to ensure that its findings are used in the service of human betterment.

The Substance and the Shadow

BERNARD M. BASS *University of Rochester*¹

In industrial/organizational psychology (as in social science, generally) we have been grasping at the shadow—but losing sight of the substance. We should attend more fully to both. Each supports the other in advancing our discipline. While nothing may be as practical for advancing technology (the substance) as a good scientific theory (the shadow), it is probable that nothing may be as impractical as a bad theory. The reverse is also generally true. Good technology may be a prerequisite for the advancement of a science. Bad practice can ruin potentially good science; it can send science on false leads and wasteful detours into fads and fancies.

Bad theories in social science often are bad in form and bad in effect. Theories may be bad in form because they are no more than speculation, propaganda, or wishful thinking. They may be bad in effect because they are premature in the time line of investigation of a phenomenon. Frequently, they are bad in both form and effect because they lack connectivity with substance—the real world of the social practitioner, artist, technician, craftsman, and engineer. Viteles (1972) pinpointed this gap between the science of psychology and its applications to social engineering. I will try to suggest some bridging processes² which

should not only strengthen real-world applications but also strengthen the science.³

Industrial/organizational psychology has arrived late at the scene for the “theory-hypothesis testing” bout with nature. The pleas in the 1950s were filled with it; the 1960s gave it to us; and now in the 1970s, we are up to our ears in it. After wallowing through “shot-gun” data gathering in earlier decades, industrial and organizational psychology was smitten by the bug for building theory and quasi theory in the past decade. Thus, motivation-hygiene theory led ultimately into an excess of job enrichment efforts, often with marginal payoffs and relatively little technical advancement in sociotechnical aspects of job design. Although some attention has been paid to the effects of individual differences in preferences, conflicts with the economic and technical constraints which impose limitations on what changes are desirable and feasible have mostly been ignored (Gomberg, 1973).

³ By science, I mean the accumulations of understandings and formulated knowledge about universals using abstract and logically compelling means. By art or technology, I mean the accumulation of workable practices and, particularly, predicted and controlled applications. As W. J. Jevons noted: “Science teaches us to know; and art, to do.” Science emphasizes doctrine, theory, and controlled experimentation; art and technology stress experience and operability. Science accentuates rationality, consistency and full systemization; technology emphasizes sensibility, reasonableness, and heuristics.

In actuality, there is much overlap. Nevertheless, it seems reasonable to agree that the organizational/industrial psychologist is acting more like a scientist than a practitioner if his activities can be labeled as basic, abstract, and theoretical. Similarly, he is more readily recognized as practicing his profession if he is applied, concrete, and empirical. There is no merit in starving one sector of research or practice for the sake of the other. Nevertheless, there often are imbalances in support for one or the other and lack of connection between them detrimental to the advancement of both (Archibald, 1970; Bakan, 1966; Bandura, 1969; Brann, 1972; Brooks, 1965; Bunge, 1966; Fishbein & Ajzen, 1972; Forbes, 1956; Fried, Gumpfer, & Allen, 1973; Margenau, 1961; Moser, 1971).

¹ An earlier version of this article was presented as the Edwin A. Henry Memorial Address at the meeting of the American Psychological Association in Montreal, Canada, August 28, 1973. I am indebted to a number of my colleagues, including Gerald V. Barrett, Enzo R. Valenzi, Ralph A. Alexander, Zur Shapira, and John A. Miller for helpful suggestions. Also helpful were Gerald Emsch of the University of Rochester and Carl E. Bennett of the Battelle Institute.

Requests for reprints should be sent to Bernard M. Bass, Graduate School of Management, University of Rochester, Rochester, New York 14627.

² Ed Henry, professor, consultant, and employee relations research director, could operate comfortably on both sides of the gap. It is fitting that this article deals with bridging the gap.

Why the Gap?

There are at least three epistemological reasons for the continuing rift between social science and social technology and the failure of social science to build from a base in social technology: (a) Social science and social technology differ in norms and goals; (b) in social science, theory is treated as an end rather than a means; and (c) social scientists ignore the differences between social and natural science. Four additional reasons are methodological: (d) We fix problem delineation and conceptualization prematurely; (e) we push for complete theorization prematurely; (f) we push for experimental rigor prematurely; and (g) we move to mathematical modeling prematurely.

Identifying the reasons for the gap will help to point out ways of bridging it.

NORMATIVE DIFFERENCES BETWEEN SCIENCE AND APPLICATION

The differential concerns of science for truth and technology for workability make it difficult for an industrial/organizational psychologist to feel comfortable, able, and willing to operate on both sides of the gap between science and application. When he does, little real bridging is attempted.

Differential values and rewards on either side of the chasm maintain it. Self-selection and selective attention to what is required for career advancement contribute as well. The science-oriented academics ignore or reject the practice-directed organizational development consultants, and vice versa.

Each side builds up self-satisfying bodies of knowledge and methods that do not take into account the results of the other's accumulations. As each body becomes more developed without interconnections to the other, it becomes increasingly difficult to open and maintain links between them. The scientist builds esoteric theories, which are mainly of interest to his scientific peers, with little attention to what the technologist is doing. The technologist, ignoring scientific endeavors and evaluations, builds esoteric skills mainly of interest to his disciples. Such vested interests increase the impermeability to contributions from across the gap. The scientist has to learn an entire new set of skills if he wants to get some understanding of the practice that has developed. He may have to reject what seemed to be some fundamentals of his science. The social technologist has to learn more

mathematics or has to deal with a set of abstractions that fail to mirror his reality.

Coleman (1972) noted a number of critical differences in the criterion requirements for applied policy-oriented research in the world of action and basic discipline-oriented research. The world of action operates in real time; the disciplinary world is timeless. Language and concepts of the world of action differ from those of the disciplines; the translation from one to the other is a key problem. The world of action involves vested interests; the disciplinary world strives for neutrality. Redundancy is useful to the world of action; parsimony is the rule in the disciplines.

Translating results of scientific endeavor into practical application often requires that the rigorous measures and constraints of the scientific effort have to be relaxed for the application. For expediency, the longer reliable test form in an experiment may become the five-minute short-form edition in practice, where it may fail to work. At the same time, social science finds it difficult to incorporate relatively weakly controlled, less reliable applications in broader real-life complex operations. For, as current social science, it is locked into a theory-hypothesis testing quest for understanding which cannot make much use of advances in social technology. A more dynamic conceptualization of scientific theory, models, data gathering, and applications is required.

SCIENCE VERSUS SCIENTISM: THEORY FOR THEORY'S SAKE

In pushing for more theory in the absence of strong technology, we have failed to distinguish between science and scientism. Theory for theory's sake is scientism, not science. Sometimes we are at a stage when more theory is needed before further understanding is possible. Other times, however, more theory may hinder rather than help. To solve social problems, social scientists conduct research to generate and test fundamental broad generalizations and to achieve general methodological solutions rather than conduct research which is less ambitious in scope and is directed at solving particular problems. Once the generalizations have been proved, it is believed that solutions to the particular problems will follow automatically. But, as Glaser (1973) has noted:

The sequence from basic research, to applied research, to development, to practice and application on which most

of us were weaned is no longer applicable if, in fact, it ever was [p. 557].

SOCIAL SCIENCE AND NATURAL SCIENCE ARE DIFFERENT

On the day of his death, Socrates criticized the natural philosophers such as Anaxagoras for trying to use the same explanations for human as for natural phenomena. It is still germane to criticize the failure to note the differences between natural and social science. While rationality is intended by both, the relative roles of theory, models, and data gathering may need to be quite different. Ordinarily, in natural science, identifiable physical mechanisms with known relations can be sought to eventually connect observed behavior with antecedent conditions. However, in social science, observed behavior usually can only be connected via inferred states to antecedent conditions. Thus, theory is in a very different role in the search for understanding the natural compared to the social sciences.

As social scientists we face much more difficulty in our search for understanding than natural scientists face. We deal with much more complex, shifting, and fluid phenomena, differing widely from place to place and group to group and often lacking stability over time (Beck, 1949; Myrdal, 1973, p. 32). It seems logically compelling that the more a country invests in growth, the more it will grow. And so economists used a capital/output ratio like a natural science constant. But now it is known that capital investment is not even a major antecedent of economic growth (Myrdal, 1973).

Differences in the utility of precision. Meehl (1967) pointed to a paradox. The very thing that may be desired and required of measurement in the physical sciences may be undesirable in the social sciences. He suggested that whenever we can and do improve the power of statistical designs, we may increase the prior probabilities to 50% of finding statistically significant differences in the theoretically predicted directions even if the theory is without merit!

The very precision that would lend confidence to the generalizability of results to support a theory from a tightly controlled, precisely measured physics experiment literally reduces confidence in the generalizability of results from a similarly tight psychological experiment to support a psychological theory. Meehl reasoned that in social science any

dependent variable of interest is a consequence of several strong effects such as genetic makeup, learning history, immediate motivation, and stimulus conditions. Superimposed on this finite list of important determiners are an indefinite, large number of random effects. For two groups not to differ, all these random effects have to balance out. The probability of such balancing is quite low. It becomes almost a sure thing that we can reject the null hypothesis by increasing the power of our design. For instance, by making samples large enough, most results will be significant. Meehl reported finding statistically significant relationships in 91% of miscellaneous, accidental pairwise associations for a sample of 55,000 Minnesota high school students.

Other differences. In the natural sciences, ideological revolutions take place in the acceptability of particular conceptual paradigms (Kuhn, 1962) but not so in the social sciences (Bronfenbrenner, 1971).

Complicating social science is the need to establish and maintain necessary expressions which "in compressed form . . . stand for complex, vaguely perceived ideas . . . about social reality [Myrdal, 1972, p. 32]." In social science, we formulate paradigms, complex sets of assumptions and beliefs that are adopted implicitly when researching a topic (Cartwright, 1973). Furthermore, although in the natural sciences value premises are simple and mostly a priori evident, in the social sciences "valuations are diversified and anything but self-evident [Myrdal, 1973, p. 34]." Nevertheless, we have tried to emulate the natural and physical scientist by constructing "utterly simplified models often given mathematical dressing [Myrdal, 1973, p. 33]."

However, the fault may not lie in the mathematical modeling and related abstract theorizing but in their premature application in much of social science before less demanding structures have been built, tested, and modified according to how well they mirror reality.

PREMATURITY OF DEFINITION AND CONCEPTUALIZATION

Premature freezing begins with the rush to define the problem to be investigated. The definition then determines not only what we will do, but what we will not do with the problem (Caplan & Nelson, 1973). Often the definition is selected because the

social scientist has the method available to study the problem provided he defines it so that the method will be applicable. Later on, he seeks problems so that he can use his method. Finally, he finds problems everywhere for which he can use his method. As Kaplan's (1964) law puts it: Give a small boy a hammer, and suddenly he discovers everything needs hammering. If you invite a people-oriented consultant into the factory, he will find people problems and needed people changes. If you invite a communications expert, he will see needed communications changes everywhere, not people changes (Leavitt, 1965). We engage in the drunkard's search. We hunt for our keys under the lamppost, because it is lighter there, not because we have any more reason to believe we lost the keys near the lamppost rather than elsewhere in the dark (Kaplan, 1964). We become "prisoners of our own procedures [Gardner, 1965, p. 47]."

We confuse our valuations of how reality ought to be with our beliefs about what it is (Myrdal, 1973). Such propaganda then excludes from research and practice alternatives focusing on other aspects of empirical reality. It excludes divergence in opinion often important in leading to more creative understandings.

The freezing tends to be extremely resistant to thawing. Once these definitions are "legitimated and acted upon, they tend to define the problem indefinitely irrespective of their validity [Caplan & Nelson, 1973]." Risky shift research is illustrative (Cartwright, 1973). The freezing is further enhanced by our deference to the credibility of authority (Becker, 1970) and the rewards for pursuing theoretical rather than applied interests (Caplan & Nelson, 1973).

PREMATURE FREEZING OF THEORIZING

"Mind-forged" manacles bind "many a gifted scholar [smothering] 'his creative talent' . . . by a growing commitment to his own previously stated doctrine [Gardner, 1965, p. 52]." Thus, if the turn-of-the-century world of physics had been more locked into theory as we may be now in social science, quantum mechanics would have been rejected by that world because it was not logical in the sense that it did not conform to Aristotelian logic nor did it do as well as Newton for macroscopic physics.

In applied psychology, too often, unchanging theories tend to be tested and retested and although

results fail to support them or give marginal support (i.e., $p < .05$, $r = .20$), the theories remain and the results are used to maintain their status over long periods, often decades. Bad theories never die, they just slowly fade away in the social sciences:

An old theory is not discarded solely because someone comes up with a better alternative: it is cherished and preserved by devout adherents until its day of resurrection and ultimate triumph, the meanwhile being made more irrefutable, generally applicable, and ambiguous with every passing year [Starbuck, 1972, p. 17].

We are not alone. "In economics, all doctrines live on [Myrdal, 1973]." But as Ernst Mach pointed out, theories ought to wither away leaving a body of empirical facts behind (Frank, 1949, p. 62).

If you read a typical study purporting to test valence-instrumentality-expectancy theory, the results do not lead to a revision of the theory. We play with a nomothetic valence-instrumentality-expectancy network. A few weak relations are overemphasized. Stronger results are discussed selectively to support a chimera followed by surprise at the empty endings. One more article is published and the next appears using somewhat different methods but trying to test the same theory.

If we do not develop a better technology and approach in this area, my guess is that after another 100 experiments to be reported in the *Journal of Applied Psychology* between now and 1980, we will actually know little more about designing specific programs to motivate workers than we do now, given the existence of Pascal's theorem published first in 1669 that expected utility is equal to the sum of the subjective probabilities of earning rewards from a designated act and alternative acts available (Pascal, 1964). Heneman and Schwab (1972) reviewed nine field investigations which attempted to test expectancy theories of motivation to work. While valence, instrumentality, and role perceptions were each significantly (but modestly) related to performance, little support was obtained for the hypothesized interactions. Poor methodology was blamed for the failures.

Yet nobody is going to question that performance depends on ability and motivation. Nobody is going to question that Pascal's expectancy theorem is plausible. The utility of research here will be in finding out how these variables combine in their effects under varying conditions. Before we can do much with these broad truisms, we need to

develop consensus among investigators and the technical facility to measure each of the variables in a variety of situations.

Theorization gets too far ahead of technology. Often in psychology, we have been trying to imitate primarily the theoretical propensities of physical science without the kind of technology that contributes so much to the development of theory after the fact or provides rapid tests of the adequacy of theoretical attempts before the facts have been established.

For instance, today, in their quest for judging the worth of academic personnel on the basis of their contributions to teaching, a substantial number of institutions of higher learning depend on student ratings to evaluate the effectiveness of their teachers. Nevertheless, Rodin and Rodin (1972) reported a correlation of $-.75$ between student ratings of the effectiveness of each of 12 calculus teachers and the mean amount learned in each of these teachers' calculus classes. What kind of science can be built with such an erroneous technology?

We put too much weight on the scientific search for universals without the equally important craft side of our enterprise. In particular, the academics among us often act like ancient Greek scientists disdaining psychological technology as opposed to psychological science. Nevertheless, technology and science are mutually dependent; each feeds on the other. The closer the coupling, the more rapid the negative feedback loops and the greater the likely progress and well-being of both. But current theories are seen as far more important than current problems—at least in the academic world. Learning about controlled experimentation and hypothesis testing is still emphasized compared to learning about how to search, select, discover, or invent technology to deal with real social problems. Yet, I argue that we will make significant contributions to the extent we can deal with real-world complexities rather than artificial laboratory problems; to the extent we can deal with ill-defined messes (Ackoff, 1972) rather than replications of prototype problems.

As John Gardner (1961) noted:

The society which scorns excellence in plumbing as a humble activity and tolerates shoddiness in philosophy because it is an exalted activity will have neither good plumbing nor good philosophy. Neither its pipes nor its theories will hold water [p. 86].

Our theories often are quasi theories. I do not

mean to imply that theorizing is necessarily bad or that theory is unessential. What I see as strangling is quasi theory couched in pseudoscientific jargon, which is usually a consequence of its being prematurely and/or poorly constructed. What is missing from quasi theories is formalization with explicit assumptions. Quasi theorists remain narrow minded and fail to see that once the logic is made explicit every piece of logic can have multiple empirical examples and every empirical example can be handled by many different logical structures. "The fallacy . . . is supposing that any single theory can capture the essence of concrete reality. . . . Logic is an infinitely rich and variable instrument [Diesing, 1971, p. 122]."

Krause (1972) applied symbolic logic to postulates that underlie cognitive dissonance to derive 25 predictions. He found that with all the empirical research that has been done in the area, only 2 predictions have ever been tested! That is, the informal logic that represented cognitive dissonance theory badly failed to convey the many alternative predictions that could be derived. What were thought to be derived were no more than value judgments. Nevertheless, such judgments constrained exploration and search in the false supposition that we were pursuing a highly logical, scientific approach to understanding.

Theoretical arguments in ordinary language move along so smoothly that there is a failure to see "the underlying logical machinery—the relational definitions, the exhaustive classifications, the tautologies [and] the hidden assumptions. . . . The theory [is treated] as a simple description of the facts . . . rather than an abstract bit of logic in disguise [Diesing, 1971, p. 121]" and seems very convincing to its proponents.

Further, since all possible facts can fit into any complete set of logical categories or any set of tautologies, there is no way of falsifying the "descriptions." Consequently as the theorist looks around for evidence to support his theory, he finds to his delight that the evidence is overwhelming. There is no contrary evidence! Everything in the world falls into place, and he comes to see that the theory is really a deep, fundamental statement of the most essential principles of human behavior. As a result he becomes the prisoner of his own logical model and is rendered incapable of seeing reality from any other standpoint [Diesing, 1971, p. 121].

Thus, Skinner "finds schedules of reinforcement wherever he directs his attention." Homans comes to see all social behavior in terms of exchange (Diesing, 1971, p. 121). And the neoclassical economists (e.g., Frank Knight, Ludwig van Mises,

and Henry Simons) "seemed to think they had penetrated to the very essence of rational human action, and that they knew whatever was knowable about it [Diesing, 1971, p. 121]."

Diesing suggested that such theorizing makes for poor understanding but good propaganda by passing off an idealized picture as a true account of reality. Facts that do not fit are quietly ignored, but the propagandist is left convinced that he is telling the truth. Kline (1962) called this *factifuging* and has detailed more than 20 ways for avoiding facts that conflict with current understanding. It may be that a premature theory in social science is like a politician and can only satisfy everyone by saying nothing (Popper, 1959).

PREMATURE OVERCONTROLLING

Our urge to be scientists leads us to ignore E. H. Moore's precept "Sufficient unto the day is the rigor thereof [Bass, 1960, p. 31]." We rush to institute controls in our data gathering before we learn what to control. Thus we may control age of subjects when age is unrelated to either the mean differences between samples or within samples. At earlier stages in a line of investigation, finding out what to control is far more important than controls for controls' sake. Just because our samples differ in age or our subjects within samples differ in age may be utterly irrelevant.

We need to avoid premature overcontrolling of expensive and wasteful effort at earlier stages of understanding in a given field. At the same time, to advance our discipline we need to give more attention to the implausibility of rival alternative hypotheses which could account for our results in early stages of model development (Campbell & Stanley, 1969).

PREMATURE FREEZING INTO MATHEMATICAL MODELING AND COMPLETE RATIONALITY

The extremes of rigidity in approach, method, and outcomes reach a zenith in the effort to bodily transfer the mathematical modeling and theorizing derived from engineering systems to understanding and controlling social and behavioral problems ranging from beating the North Vietnamese to delivery of hospital services (Hoos, 1972).

This is not to say that the linear and nonlinear programming models and so on are in themselves inconsistent or invalid for understanding the physical systems for which they were developed. Rather,

the experience, judgment, values, and accumulated understandings of the social scientist must be brought into play in the many approximations and estimations required for these models to begin to have any chance of replicating social and behavioral reality (Hoos, 1972). Otherwise, they become like the Walras model in economics, forms of analysis without much substance (Samuelson, 1952).

Unfortunately, the lack of factual knowledge of conditions existing in the real world forces the model builder to base many if not all of his general conclusions on all kinds of *a priori* assumptions, chosen for their convenience rather than for their correspondence to observed facts [Hoos, 1972, p. 37].

Will applied psychology go the way of economics and become increasingly the province of the mathematically anointed dealing with shadows rather than substance? You may think I have created a straw man rather than a real possibility, but keep in mind that organizational/industrial psychologists are increasingly finding employment in business schools where economists often form the dominant faction. It may be difficult for many of us to avoid slipping into the same fallacious activities as a consequence of interdisciplinary pressures toward conformity which can exist in academia.

The costs to society as well as to social science of the premature modeling and theorizing were learned through the bitter experience of Southeast Asia where an enemy played by its own irrational (to us) rules rather than ours. The costs are continuing at home where we are seeing the economist who believes himself to be completely rational becoming "the expert in all aspects of public planning, whether the area be health, education, urban redevelopment, or construction of low-cost housing [Hoos, 1972]."

Apparent rigor and certitude of economic analysis, its models and its mathematics, have been allowed to outweigh other outlooks and methods more pertinent to reality. In the interests of simple solutions to complex problems, an economist can seriously argue that city centers ought to be allowed to deteriorate in value so that their price to developers becomes low enough to enable the latter to profitably redevelop the area. Ignored are all the social, cultural, and political costs of allowing such a process to occur.

Ways to Bridge the Gap

What I want to do is show how investigators ought to approach reality and how the mathematical

models ought to appear only after much earlier work has been accomplished.

I offer 10 interdependent guidelines to pass over the pitfalls dug by assuming too much similarity between science, social science, and social technology and to bridge the methodological gap caused by a too hasty rush to complete systematization: (a) hang loose; (b) strengthen informational links; (c) advance our technology as we advance our science; (d) be open to more issues at the interface of science and technology; (e) make more use of technical assignments; (f) consider the relative state of the science and the technology; (g) change our statistical usages; (h) increase the fidelity of the variables we investigate; (i) use multiple investigatory approaches; and (j) teach both science and technology.

HANG LOOSE

The path to useful definition, conceptualization, and theory construction calls for more work in wallowing around in reality and more openness to experience prior to being frozen into a narrow statement of the problem, rigid conceptualization, a parochial methodology, turgid theorization, and "mathematical dressing." Rogers (1973) may be saying much the same thing with more feeling when he calls for a more humanistic science of psychology.

From exploration to systematization. For a metaphorical prescription for what I mean by hanging loose, I am indebted to Gerard Emch (personal communication, April 1973):

1. An area of ignorance is to be conquered. Paratroopers are sent in who do not necessarily even know on what or where they will land. There already may be some rudimentary road maps and guidebooks available, but the need here is for openness to reality, for avoiding premature closing of leads and hunches.

2. The long-range artillery is brought up for global attack. They depend, of course, for information feedback from the paratroopers.

3. Ground forces fully occupy the territory.

Improvable definitions. Hanging loose implies looser definitions at earlier stages in the time line of investigation. Definitions are always improvable. In the light of new data we modify old definitions. When an accepted definition proves inadequate to handle the many exceptions that emerge both in the laboratory and in the field, we

modify it. The exclusive categories of matter as solid, liquid, or gas give way to handling the discoveries of new forms such as plasma (Stevens, 1951).

More trial and error. Hanging loose implies encouraging trial-and-error problem solving by behavioral technologists to give chance more of a chance. We would like to believe that science advances mainly by constructing models that generate testable hypotheses. In fact, serendipity plays a much more important role in some fields, although not in all. Jacques Monod (1971) suggested that most of the discoveries in biogenetics have been serendipitous. However, Platt (1964) argued that the advances in molecular biology are a consequence of rigorous application of strong scientific methodology. I surmise serendipity is a particularly significant factor in organizational/industrial psychology.

Before we make large-scale investments in social programs, we need to invest a longer period of trial and error in engineering and re-engineering simulations or small field demonstrations of what we hope ultimately to introduce. Going from deductive models or from laboratory studies directly into the field with a large-scale innovation seldom works. We need to spend much more of our time, energy, and resources in the field, working as real systems tinkerers and cooks, trying to establish generalizations from our experiences in efforts to make a sequence of small changes in the system in which we are interested. Over 40 job-enlargement experiments are being carried out among more than 1,500 workers in one Volvo plant I recently visited. The new job designs are created out of management-worker discussions, with a few primitive models⁴ in mind requiring simple changes in task

⁴ A *theory* is a systematic, generalized explanation of some part of reality that is scientifically acceptable; a *model* is a simplified representation of reality instead of a broad explanation. Theory generalizes to all cases; models cover a few specific situations (Starr, 1971). Models can be simple lists of possible factors of consequence or they can be complex arrangements specifying functional relationships between variables and constants.

Starr described three increasingly complex models:

1. A shopping list designed to increase a family's happiness is a primitive model. It may include soap of an unspecified brand, size, and price, as well as coffee of a particular brand and amount. Satisfaction can be expected to depend on price, taste, and shopping convenience. Factors can be combined to achieve specified objectives. Variables can be changed in amplitude and intensity.

configurations. Ultimately complex theory may emerge in this area, but for the present, trial-and-error advances in technology seem much more productive.

More problem focus and subjective orientation. Edwin Land ("Edwin Land," 1972) has noted that if you can completely identify the problem, it can be solved. That is, if you know the elements of consequence in the particular situation and how they affect each other, you are well on the way to solving the problem. In social science, you also may need to know how the elements of the problem affect you. Investigators need to give more credence to their own observations, sensations, feelings, as well as those of other astute observers who have tried to articulate the nature of the problem and have proposed models for representing the problem (Rogers, 1973). Out of this can emerge a primitive model listing the variables expected to be of importance as well as how to measure and dimension them.

Revisionistic thinking. By beginning with problems—of which there is no scarcity—and then concentrating on model building and model testing with the expectation that the model will be improved with each inductive test, we will approach better solutions of the real problem for which the model is in incomplete representation. Tests ought to be designed so that whatever their outcome, a revised model will emerge which in turn will contribute to changing the related broader theory.

If we want to use a priori thinking before data collection with some profit, what we need as applied psychologists is to think more in terms of transitional models, "each giving way to a succession of simpler and empirically more accurate models under the guidance of research findings [Heller, 1972, p. 19]." The transitional models can become in-

creasingly complex as we progress down the time line of investigation. A deliberate policy of revision is entailed as well as location of the boundary conditions for the validity of the developing model.

Tukey and Wilk (1965) underscored the need to stay loose with one's models and theories when they speak about the common requirements for good experimentation and good data analysis:

some ideas [in advance] of a model, are virtually essential, yet these must not be taken too seriously. Models must be used but must never be believed. [Furthermore] data analysis, like experimentation, must be considered as an open-ended, highly interactive process, whose actual steps are selected segments of a stubbly branching, tree-like pattern of possible actions [pp. 9-10].

Myrdal (1973) observed that "facts kick, even if somewhat belatedly, when data have been assembled under inadequate categories [p. 35]." We need to be ready to receive the kicks to revise our categories. We need to be able to revise our models to fit the facts rather than revising our methods to fit the models. This calls for solid fact finding, for becoming technologically proficient in establishing empirical facts before we try to move from models based on laboratory and survey fact finding to social engineering. At the very least, we need to build and revise transitional models as we move from survey and experiment into the field.

More consensus on measures. If different investigators are able to employ the same standardized but improvable measures (see Barrett, 1972) with reasonable confidence in their validity, the beginnings are available for constructing a useful theory, one which transcends a variety of situations, rooted in already successful problem solutions. As noted earlier, all too often we tend to start theorizing prematurely with little preceding modeling to provide some minimum confidence in the reliability or validity of what we purport to connect together with our theory. And failure to attend to the adequacies of one's measurements can lead one far astray following what he would like to find in reality, not what he really finds. The Tosi, Alda, and Storey (1973) reexamination of Lawrence and Lorsch's (1967) seminal study is illustrative. Expanding on Kelvin's dictum (Wheeler, 1956) that if you cannot measure it, you do not know what you are talking about: *If you cannot measure what you are talking about, no amount of theorizing will put you any closer to understanding the real world.*

Delay serious deductive efforts. It is only in the third stage of exploration to systematization that we should begin trying to be fully systematic and

2. An intermediately complex model specifies relationships such as $y = f(x)$. It also posits a priori that given outcomes will depend on given antecedent conditions. For example, the model can specify that the amount of coffee purchased will be a function of the amount remaining on the home shelf, the amount of coffee drunk each day, and the frequency with which the shopper visits the grocery store.

3. The most complex model has feedback which alters values of the variables of the model. Relationships can be changed based on the data gathered. For example, price rises may force family discussions about continuing to purchase the particular brand rather than turning to a less expensive one. At this point we probably are ready to start formal theorizing with some purpose.

thoroughly deductive. Thus, Tukey and Wilk (1965) noted that:

While detailed deduction of anticipated consequences is likely to be useful when two or more models are to be compared, it is often more productive to study the results before carrying out these detailed deductions [p. 10].

Furthermore, they argued that:

In both good data analysis and good experimentation, the findings often appear to be obvious—but generally only after the facts [p. 9].

It is at this time in a line of investigation that we become capable of building a formal theory. As Kline (1953) noted:

Logic . . . sanctions the conquests of intuition. It is the hygiene [which helps] to substitute intuitions more consistent with the mass of ideas than currently stated thoughts [p. 408].

It would be nice if we could base our models on theory but *it is more likely that useful theories will emerge if we first have been able to construct some reasonable models of the behavior we are interested in theorizing about.*

STRENGTHEN THE INFORMATIONAL LINKS BETWEEN
SOCIAL SCIENCE AND SOCIAL TECHNOLOGY

Robert Glaser raised my consciousness about these matters at the 1972 APA meeting when discussing my revising *Training in Industry: The Management of Learning* (Bass & Vaughan, 1966). He said that the first half of the book dealing with a traditional overview of learning, motivation, and perception needed considerable augmentation. In its present form, it is mainly a list of variables which need to be considered by anyone interested in designing an applied training or development program. It needs to provide better bridges from

learning to training, a straddling between laboratory and field. Glaser (1973) has elaborated on the need for this interactive mode of research in education and educational psychology.

Unfortunately, few of us are effective straddlers. More ought to be. But more important we need to develop mutually influencing linkages between social science and social technology.

Problem-centered social technologists have a lot to offer to those interested in fundamentals. In turn, the social scientist may offer much guidance to social technologists. For both, much creative work proceeding from exploration to systemization lies ahead with transitional models representing the areas in which they both are working. Note that I reach this without one word about relevance. From this point of view, the fact that the research approach I propose may be more relevant is a happy coincidence. It may also mean that what is relevant in a single instance has greater possibilities of contributing to generalities which will hold up across many instances. To say something is irrelevant may also mean it has limited potential for contributing to generalization across instances.

The contrast between this proposed relation between scientists and technologists and the arrangements more often thought to exist is schematized in Figure 1a. In Figure 1a, scientists spin around their own axis building models increasingly closer to the truth until one can be spun off to social technologists, who then develop successively more workable models. This is the science-to-application approach which I have already noted is more fiction than fact. In Figure 1b is an approach with more promise of connecting needed applications with basic science. Successively more complex models increasing in both truth and workability flow back and forth between scientists and technologists. The

Figure 1a. Ineffective relations between social scientists and technologists.

Figure 1b

Figure 1b. Effective relations between social scientists and technologists.

gap between them tends to close as the models increasingly reflect the contributions of both.

What I propose for industrial/organizational psychology is consistent with what is now recognized as the appropriate relations between science and technology.⁵ On occasion, in the physical sciences, theoretical insights have preceded technological advances. Einstein's mass-energy equation preceded the practical conversion of mass to energy. But just as often, contrary to popular belief, much of theory in the physical sciences created unifying but after-the-fact explanations of what physical technology had already reliably demonstrated. Thus, "flight by machines heavier than air was still being declared impossible by eminent scientists when in 1903, the first airplane was unexpectedly lifted into the air [Brinkman, 1971, p. 125]." Again, "[Gail Borden] did not know enough to be confused by the theories [of his day, the 1850s] which proved that [one could not condense milk]. . . . He simply went ahead and did it [Boorstin, 1973, pp. 27-28]."

Many times technological advancements were made based on false scientific assumptions. Thus, Watt built his steam engine as an adherent of the phlogiston theory (Brinkman, 1971) and Agassi (1966) claimed that even today "we do not believe but we still apply Newtonian mechanics [p. 364]" which does not work very well for micromechanics.

More than the practical application of science, technology is a "mode of disclosing" of a particular world and making it manifest according to Heidegger (Alderman, 1970). In advancing tech-

nology we advance science and in advancing science we advance technology (Skolimowski, 1966).

What the executing hand taught the head was used again for the better guidance of the hand. Thinking followed the action and was at the same time a pre-thinking of the next action . . . knowing and making began to aid each other and it did not take very long before physical science and technology discovered that they essentially belonged together [Melsen, 1961, pp. 224; 241].

A good case in point in industrial/organizational psychology is change agency. Much is being written about what change agents should do. The prescriptions mainly derive from the values of the prescribers and extension of surveys and experiments loosely connected to past practices and personal experiences. Change agents often claim they are being guided by theory, but as Tichy and Hornstein (1972) noted, most change agents are artisans rather than scientists. This does not mean they should be dismissed or ignored by those interested in scientific understanding of organizational change. Tichy (1972) identified four types of change agents with both similarities and differences in values, approaches, methods, and objectives: outside pressure agitators, top-down efficiency experts, organizational development craftsmen focused on improving the organization's problem-solving capabilities, and people-change artisans working to develop increased individual skills and satisfactions. Knowing this gives us the rudimentary beginnings for modeling alternative organizational change efforts and proceeding to appropriate next steps to understanding the change processes.

Figure 2 shows (with the heavy arrows) the informational links between social scientists and technologists that need particular strengthening. Tichy's work represents one attempt to start doing so. Some of us devote ourselves to trying to confirm the validity of a model. Others see a better technology as an end product. We should be clear that spending all our time and effort on one will

⁵ Noting the differences between science and social science and then using the history of science to illustrate directions for social science may seem contradictory. This is not so. The differences call attention to the fact that the lessons of science may need qualification when applied to social science to the extent that both are quests for rational understanding but are about different subject matter.

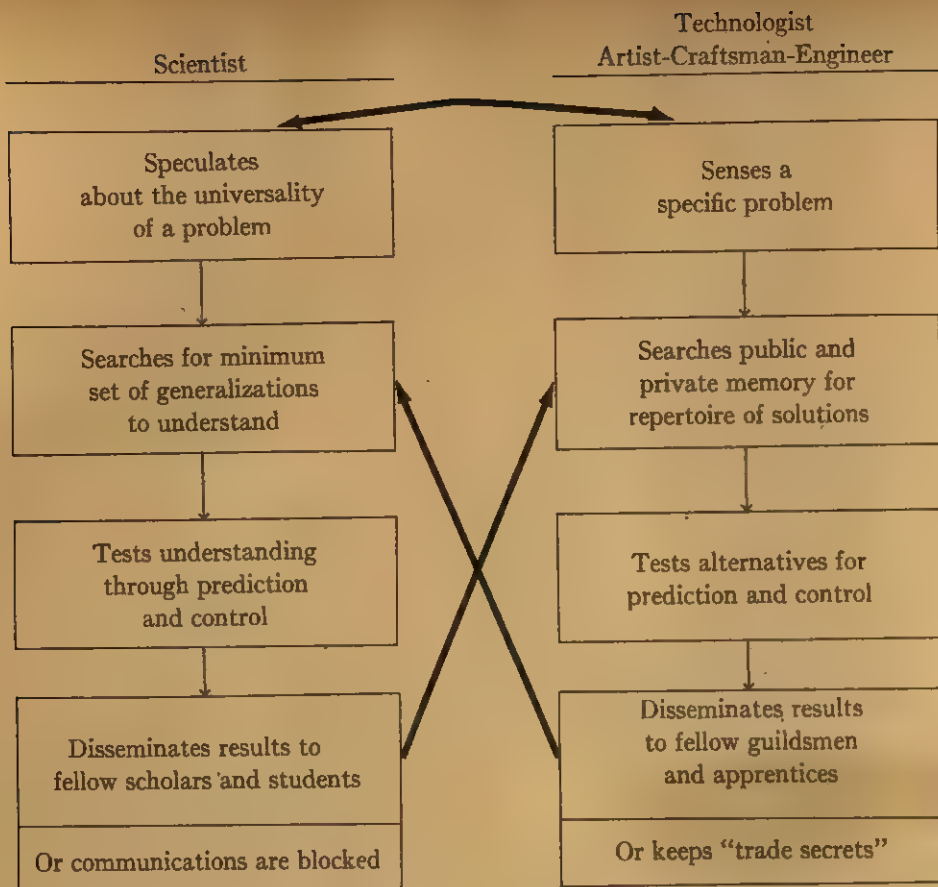

Figure 2. Informational links that need to be strengthened in the social sciences.

not necessarily directly advance the course of the other. The connection must be made. Subscribing to this position, Glaser (1973) sees that the times are ripe and society more open than ever for experimentation and innovation which will make it possible for educational psychology to move itself forward in this way.

ADVANCE OUR TECHNOLOGY AS WELL AS OUR SCIENCE

How much attention do we pay to our paratroopers in industrial/organizational psychology? How often do we even hear from them publicly? How do they make themselves heard? Our science tries to occupy the unknown territory with full systemization long before we have much sense and measure of what is really going on in the territory, long before we have tried a series of progressively better models to give us clues as to what direction a formal theory will have to take.

Industrial/organizational psychology needs to support its paratroopers, artillery, and occupying

forces. All three can be linked via transitional models. The paratroopers discover the variables for the models; the artillery, the functional interrelations; and the occupying forces found theory on the complex models which, after many iterations, have become stabilized replicas of reality. This, I see, provides a considerably different approach to relating basic science to applied technology.

It is not that we do not have many social technologists. It is that we have been unwilling or unable to connect what they do and what they learn (or think they learn) with what we social scientists should be doing if we seriously want to ultimately understand the realities of social science. We particularly need to become aware of the different criteria of success that govern much of the social craftsman's efforts compared to those of the social scientist (Coleman, 1972).

We must recognize the need for some of us to pursue technological efforts from which learning can accrue and be made public. Mastery of the unknown concerning a behavioral phenomenon, particularly one likely to be sensitive to the con-

textual situation in which it was embedded, would grow from iterative trials leading to a better and better model for specifying how to predict and control the phenomenon. Thus we need a much strengthened technology for search and delineation of behavioral problems, for behavioral modification, and for evaluation of the effects of social engineering. Laboratory models can only provide suggestions to stimulate our search and inventive process.

It should be clear that at the core of behavior change lies some applicable principles like operant conditioning. But one might argue that Skinnerian science is good mainly because it has initiated the establishment of a reliable technology and bad to the degree it has diverted attention and effort away from developing alternative technologies which derive from other theoretical perspectives.

Instead of expecting and hoping to move from laboratory-based experimentation into social engineering, we see applied problem solving and basic and pure research moving along side by side. I argue for equal rights for problem-oriented paratroopers, not because what they do is more relevant but because what they must do is as important to the advancement of the science as the theory construction and theory testing engaged in by the occupying troops. It is interesting to note that the first time we made some lasting progress in the psychological study of supervisory leadership was when C. L. Shartle (1952) and his Personnel Research Board at Ohio State in 1945 began pushing the need to study systematically as a job analyst what real supervisors do. Many factor analytic studies by Hemphill, Stogdill, Halpin, and Fleishman lay between the 500 or more descriptive items originally collected and the two-factor 44-item Leader Behavior Description Questionnaire (Fleishman, 1953). (By the way, we now know it is time to go back and look at many of the areas and items which got lost in the distillation process [Bass & Valenzi, 1973; Miller, 1973].)

Instead of diverting the time, effort, and resources of applied social science with hasty systematization we must concentrate on fostering the discovery of the myriad of phenomena "out there" sensed "in here" that are of consequence to us. More of us need to concentrate on observing, thinking, and articulating what we see around us to contribute to the health and well-being of our discipline. Good models are still needed, but for applied psychology they must be couched in terms of real-world observables and must be subject to

correction and modification as they are tested in the real world.

It is true that we need to develop umbrella-like connections between constructs of consequence as well as several different approaches to indirectly sensing or observing the construct. But why should these several approaches not be the subject of careful standardization subsequently to be used by all investigators interested in the particular area of study in which the construct is located, as Barrett (1972) has suggested. Current concerns for theory building and hypothesis testing might well await better measurements and agreement on the real-world facts about which we are trying to theorize. Thus, Glaser (1973) suggested that a good introduction for students interested in the psychology of training and development would be to identify programs of instruction that have been found to work well, i.e., that are technologically sound. Differentiating these from programs that have failed to work might provide a better basis for furthering study and application of principles which might be abstracted. Glaser did not deny the importance of undirected basic research but he also placed importance on the

intuitive design of educational practices by outstanding teachers. Good practice has an artistry and intuition which must not be restricted and which may far outrun any momentary attempts at definitive understanding and analysis. Ideally, our job as educational psychologists is to work within these two extremes, contributing to knowledge and practice, and trying to understand both without inhibiting either [p. 557].

It is in this interactive mode that Glaser sees many individual researchers now working on such topics as subject-matter learning, the teaching of basic abilities and aptitudes, adaptation to individual differences, and testing and measurement.

Admittedly, there is a danger here of relying only on raw empiricism. We may not understand why a particular training program works. We then will be tempted to apply it across the board to many situations in which it will not work and then, in an attempt to explain the preordained failures which result, churn out complicated, after-the-fact "theories" which duplicate the superstition paradigm. Thus, in the application of behavior modification, the faithful technologist may feel it is necessary to follow the techniques devised with pigeons when he deals with humans who have a much richer stimulus-response repertoire. For example, he may:

spend countless hours patiently shaping behavior bit by bit when much of this tedious process can be drastically reduced . . . through graduated modeling combined with positive reinforcement for matching responses [Bandura, 1969, p. 233].

BE OPEN TO MORE ISSUES AT THE INTERFACE OF SCIENCE AND TECHNOLOGY

We ought to direct particular attention to problems that lie at the interfaces of what we have heretofore dealt with in more narrowly confining ways (Bass, 1968). For example, as behavioral scientists we may decide that instead of one more technological analysis of the reliability and validity of selection boards in comparison to the reliability and validity of bosses' appraisals in bureaucracies for assessing management potential, we would focus on the differential effects of selection boards and bosses' appraisals on managerial performance. Is less toadying done if one is beholden to a board of superiors for one's promotion, such as in the state department or the military, than if one is beholden only to one's own boss for promotion, such as in civil service? How does this, in turn, affect the reliability and validity of board decisions and bosses' appraisals?

Perhaps it is this greater openness to issues, as well as shorter circuitry requirements for information links between the real world of action and the disciplinary world, that accounted for Gordon and Marquis' (1972) finding that medical sociologists working in academically marginal settings (health agencies, hospitals, or medical schools) were three times as likely as their higher status university colleagues to produce extremely innovative studies (Starbuck, 1972).

MAKE MORE USE OF TECHNICAL ASSIGNMENTS

Technology can be better incorporated in our science if we do more to make use of engineering, consulting, or technical assignments as a location for learning that ultimately may lead indirectly to scientific advances.

Rather than seeing these technical assignments only as low-grade services unlikely to ever contribute to science, we should regard these as opportunities to tinker, to conduct quasi experiments, to experience, to wallow around in the muck of the real-world complexities to give us insights which we may later find useful to bring under suitable control.

CONSIDER THE RELATIVE STATE OF THE SCIENCE AND THE TECHNOLOGY

There is a time for scientific theorizing in an area of study. There is a time for technological advancement. For instance, London (1972) ably summed up the current need in behavioral modification study for concentration on technological rather than theoretical efforts. He saw as needed

the systematic exploration of all kinds of therapeutic things without inhibition or concern as to whether they fit ostensible principles of learning, or reinforcement or whatever, but with a single focus on whether they fit the facts of human experience. . . . We have gotten about as much mileage as we are going to get out of old principles, even correct ones, but we have hardly begun to work the new technology [p. 919].

The psychologist concerned about understanding real industrial/organizational problems should ask first if available models and concern for experimental verification of these help or hinder his efforts to search and discover optimum solutions to his problems. He then should proceed with a complete problem-solving strategy of search and invention within cost constraints to test the extent his solutions solve the problem. The "establishment" of journal editorial boards, graduate schools, and granting agencies should support these efforts as completely as they support model building and testing. There is some optimum mix depending on the state of the area of inquiry. We need to increase extensively our knowledge of what in fact are optimum shaping strategies for given problem situations and how to aid in designing optimum programs for doing so.

Again, for organizational/industrial psychology as a whole, at this time I think we need technological invention, study, and examination as well as theory construction and controlled experiments to verify or refute theoretical models.

CHANGE STATISTICAL USAGES

Transitional modeling suggests changing the character of our statistical testing. C. E. Bennett (personal communication, April 1, 1973) noted that we tend to use statistics like a drunk uses a lamp-post: for support, not illumination. To sober up, we need to start thinking more in the Bayesian approach and less in the classical Neyman-Pearson approach to the use of statistics. That is, supposedly verifying the fleeting appearance of a phenomenon at the 5% level will not advance the

science much. But deciding whether to change an element in a model will. Statistical analysis ought to be seen as more of an aid in decision making rather than as a way of verifying some fundamental theoretical position.

The difference between the classical Pearson-Neyman use of statistics and the Bayesian approach lies in both the exploration and confirmation of hypotheses: In the classical approach, previous experimentation is used to design the new experiment but one's conclusions strictly depend on the extent the new experiment departs from a particular model of randomness. In the Bayesian approach, the data found in exploration are used along with subjective information to make explicit one's expectations. It is against this accumulated knowledge that confirmatory tests are run.

A paradox lies in hypothesis testing itself. According to Bakan (1966) our archives are being filled with false information. He reasoned as follows: Consider the case where the null hypothesis is actually true, that is, no difference really exists between two treatments. One hundred psychologists run experiments to reject the null hypothesis. Of these, 5% succeed and 95% fail. Who publishes? The 5% who rejected the null hypothesis submit manuscripts which are accepted by the journal editorial establishment. The journal duly publishes five independent studies rejecting the null hypothesis when truly there was no difference to report (Bakan, 1966).

Some serious rethinking is posed by Meehl's (1967) paradox noted earlier and related malpractices in behavioral science. In private communication (February 27, 1973), Meehl indicated that he is looking at how to deal positively with five malpractices he noted (Meehl, 1967) of behavioral scientists: (a) equating confirmation with refutation of theories (equating rejecting the null hypothesis at the 1% level of confidence with supporting the theory derived from the hypothesis at the 99% level of confidence); (b) ignoring the true weakness of statistical tests for the purpose; (c) exploiting a posteriori explanations of failures; (d) introducing auxiliary assumptions to account for failures; and (e) challenging of a succession of after-the-fact hypotheses, occupying a position of a "potent-but-sterile intellectual rake, who leaves in his merry path a long train of ravished maidens but no viable scientific offspring [Meehl, 1967, p. 33]."

To these malpractices could be added another: locking ourselves into the use of the wrong statistics to treat hypotheses that have emerged from our informal theorization. For instance, we propose multiplicative formulations and then use analyses of variance which are clearly additive in all their conceptualizations.

INCREASE THE SPECIFICITY AND FIDELITY (THE REAL-LIFE CHARACTER) OF VARIABLES

The three-stage pattern for the growth and interlacing of social science and social technology suggests that we begin with studying specific problems in specific locations before moving too quickly into abstractions. Models with general applicability are more likely to develop out of such beginnings.

Dissatisfied with inconsistent results of job enlargement programs based on theoretical considerations, one large firm essentially returned to the beginning of the three-stage pattern. Currently it encourages self-planning by teams (see Bass, 1970) and studies the effects on a case-by-case follow-up to see what self-planning works and what does not. In short, instead of a push toward job enlargement with implications that everyone wants a bigger, more self-actualizing job that can be automatically provided, the approach is to make reorganization self-guided—and to learn better ways of doing it.

We can also draw into our experiments more faithful replicas of reality to manipulate. Hawkes (1972, 1973) described the design of basic research with hypotheses and variables drawn from real-life operational observations:

It is possible to design good basic research with selection of parameters based on analysis of operational situations ("real life"), hypotheses on the functions involved, and laboratory studies on these functions. . . . In designing your research you can ensure better generalization to applied areas as we build the data base of psychology, if the environment outside the laboratory is viewed as a source of appropriate values for your variables [Hawkes, 1973, p. 269].

A good illustration is provided of how to increase the linkage between the field and the laboratory and the generalization of results to the field. Instead of using white noise as a background distractor in discrimination learning, traffic recordings were employed. Hawkes (1973) went on to cite three examples where this was done with profit: to study time perception, background noise, and ego involvement.

Another implication is that we need to begin to act on what Cartwright (1973) has so ably pointed out in his case study of research on the risky shift:

After 10 years of [laboratory] research [and almost 200 journal articles], Stoner's original problem remains unsolved. We still do not know how the risk-taking behavior of "real-life" groups compares with that of individuals. . . . The answers to such questions are not much clearer now than they were 10 years ago [p. 231].

Both field and laboratory research are needed. It is with this reasoning that my colleagues and I have begun two major research efforts. In one effort, we have been engaged in looking at what can be done to make work more attractive to the worker. Using Smith and Kendall's (1963) allocation procedures we have been able to identify 37 conceptually different variables in the way work is done which are likely to affect worker satisfaction. We are now trying to develop suitable scaling procedures to put into the hands of job and organizational designers. From this primitive modeling stage should grow more complex models ultimately leading to the furtherance of theory as well. In tandem, we have constructed a laboratory simulation in which we will be able to manipulate some of these variables which we have located in our field studies.

In the same way, we are looking at management styles. We began with a primitive model, a long list of variables concerning the manager himself, his subordinates, the task, and the external and internal environments of the organization and the work group, which are known from laboratory and survey evidence to affect whether a manager is participative or directive. We have developed reliable measures of five conceptually distinguishable styles: direction, manipulation, delegation, consultation, and participation. We have constructed comprehensive survey instruments about organization, task, and person of consequence to leader behavior. At the same time we have created a parallel laboratory simulation to permit manipulation of many of the variables of consequence. Our aim is to develop a more complex model for which we also have the technical capabilities of measuring each of the variables of the model with reliability and validity. We intend to move back and forth between laboratory and field using the same real managers as our subjects (Bass & Valenzi, 1973).

A last implication concerns our own pedagogy. Many obvious inferences can be drawn from the preceding discussions. But several extensions can be offered here. Ed Henry was successful because he could talk the language of the managers of his day. Increasingly the managers and decision makers of tomorrow will be steeped in the technology of operations research and in Bayesian analyses which will force us to be explicit about our assumptions and value judgments. Our failures will be more readily seen.

Ultimately, many managers will reach the level of sophistication to deal with the messes, the Jamesian blooming, buzzing confusion they face from total systems rather than the clearly defined problems of the system subparts which can be solved mechanically (Ackoff, 1972). Such managers will be aware of the chimera represented by optimization, single objectives, and single solutions to complex messes. They will be trying to handle the total system as an adaptable organic whole with interrelated parts. Our students will need to be able to communicate effectively with such managers. Our curricula and some courses, at least, ought to emphasize delineation of ill-defined problems and messes as well as dealing with them as craftsmen and scientists.

Ed Henry worked hard to try to create psychological internships in industry. Some success has been achieved; more is needed. At the same time, opportunities need to be developed in the school situation for students to practice delineating problems, trying out techniques, and engaging in creative opportunities.

To illustrate how I try to promote this, each student in a training and development seminar I run determines a training need in an adult sample, designs a program to meet the need, administers it, and evaluates it, presenting reports on why he used the methods he did and what alternatives based on literature review and experience he could have tried but did not. At the end of the course, students hopefully have increased their technical competence as training program designers, at the same time as they have become aware conceptually of the classes of variables to which they had to attend at each stage of the game. Stimulus conditions, behavioral repertoires, and feedback loops are concretized. Specific models are emphasized rather than global theories. The phenomena of

consequence are seen, probed, documented and manipulated.

Conclusion

What have I tried to say here? First, I think we need to delay locking ourselves prematurely into complex theorizing, defining, and hypothesis testing before we have adequately, fully, and openly looked at the problem to which we address ourselves. This does not mean raw empiricism and a rejection of theory. It means theory commensurate with where we are in the process of studying our problem.

Second, I think that as much as possible we need to look at real-world data for the source of our problems and to bring into the experiment data that we solidly connect to the real world. This will enable us to seek valid generalizations in real-world operations of what we can accomplish in controlled experimental settings.

Third, models and theories that do not yield tests of their revision hinder understanding of a problem more than they help.

Fourth, industrial/organizational psychologists should play a crucial role in advancing the science of psychology if they can straddle or work on teams that straddle from operations to laboratory in promoting the understanding of problems of human abilities, motivations, and interpersonal behavior.

Applied psychologists are men in the middle. Some of our colleagues in more general areas see us as soft, inexact, and muddleheaded; the laymen who "meet payrolls" with whom we must deal see us as hard but impractical, academic theoreticians grasping for the shadows rather than the substance. We need to learn how to do both.

Culture and Achievement Motivation

MARTIN L. MAEHR *University of Illinois, Urbana-Champaign*¹

The study of culture and behavior has regularly prompted a concern with variation in achievement motivation. Whether the focus is on growth and change in national groups, the characteristics of minority subcultures, or the behavior of individuals, it is widely assumed that achievement is not just a function of capacity, opportunity, or good fortune. Rather, it is believed that "where there is a will there is a way," and therewith achievement motivation has emerged as a popular explanatory concept.

This concern has been epitomized in the work of David McClelland (1961, 1965a, 1965b, 1971a, 1971b, 1972; McClelland, Atkinson, Clark, & Lowell, 1953; McClelland & Winter, 1969); indeed, no one is more closely identified with the study of culture and achievement than he. But McClelland's work typifies what may well be a critical shortcoming in the research thus far. Based on a conceptualization of achievement motivation in which stress is placed on learned inner drives and culturally derived personality patterns, his work has given limited attention to the situational contexts that affect achievement. The possibility that achievement may take a variety of forms and be pursued to differing ends has really not been fully explored. Further, it has perhaps been too readily concluded that certain cultural groups are lacking in motivation as far as achievement is concerned. Just as recent work in linguistics and cognition (e.g., see Baratz & Baratz, 1970; Bernstein, 1970; Cole, 1972; Cole & Bruner, 1971; Ginsberg, 1972; John, 1972; Maehr, 1974; Shuy, 1969) has raised serious questions about the cultural deprivation

assumptions implicit in the study of intellectual development among some cultural groups, so a similar line of questioning may be desirable with respect to motivation.

In any case, this article suggests a framework for the cross-cultural study of motivation that stresses the importance of contextual conditions in eliciting achievement motivation and emphasizes cultural relativity in the definition of the concept.

The Nature of Achievement Motivation

In general, the term *motivation* has referred, in the first instance, to inner states or processes of the organism—needs, drives, etc.—which prompt and guide behavior. Concepts of achievement motivation have likewise laid considerable stress on the workings of inner dynamics. However, it may be profitable, initially at least, to ignore these inner workings and to concentrate specifically and directly on the behavior that is taken as indicative of motivation. At the least, such an approach should probably yield less disagreement as to the object of consideration. More importantly, this approach will suggest what amounts to a different framework for the study of motivation.

The study of motivation, then, might well begin with a taxonomy of *behavioral patterns* that are typically placed under the rubric "motivation." Such a taxonomy of behavioral patterns which characteristically prompt motivational inferences would most certainly include three readily identifiable routines: change in direction (choice), persistence, and variation in performance when capacity is in some sense controlled. The study of motivation could profitably begin with these more or less readily identifiable behaviors rather than with postulates regarding inner states, psychic energies, predispositions, predilections, etc.. These are the basic data, and quite possibly the study of motivation ought to be candidly defined as the study of certain specifiable *behavioral* routines, such as persistence, change in direction, and selected cases of variation in performance. But regardless

¹ An earlier version of this article was presented at the conference of the North American Society for the Psychology of Sport and Physical Activity, May 15, 1973. The stimulation, criticism, and support of the University of Illinois Committee on Culture and Education is gratefully acknowledged. Support in the writing of this article was also provided by the University of Illinois Center for International and Comparative Study.

of how motivation is generally defined, this is the way it will be defined here.

Given this definition of motivation, the business of motivational theory is basically one of developing effective schemes for determining when and under what conditions persistence, change in direction (choice), or variation in performance will occur. Three strategies can be followed. In an important sense they are overlapping strategies, and one strategy cannot be considered exclusive of the other two. In the present instance, however, it is helpful to define these strategies separately.

1. A first strategy may be expressed diagrammatically as follows:

where C = "culture," or, more specifically, the social learning experiences provided by the milieu in which the person develops; P = "personality," or some assumed predispositions to respond in a given manner; M = observed tendency to exhibit in a variety of situations that behavior termed *motivation*.

2. A second strategy may be diagrammed as follows:

where S = a situation or context that has demonstrable effects on motivation; (P) = "personality," but placed in parentheses () it refers to the relative unimportance of this variable in the present scheme. That is, presumably the interest is in this aspect of S irrespective of personalities; M = an observed behavioral pattern.

3. A third strategy in some sense represents a combination of the two foregoing strategies. It may be diagrammed as follows:

Briefly, it is assumed here that social learning (C) does eventuate in certain personality predispositions (P) and that these patterns eventuate in different motivational behavior (M) depending on the situation or context (S).

When the term *achievement* motivation is employed, study is then restricted to certain conditions under which these behavioral patterns occur. More specifically, achievement motivation refers first of all to behavior that occurs in reference to a *standard of excellence* and thus can be evaluated in terms of success and failure. A second defining condition is that the individual must in some sense be *responsible for the outcome*. Third, there is

some level of *challenge* and, therewith, some sense of uncertainty involved.

Since this approach to defining achievement motivation is so self-evidently in debt to the McClelland tradition, it may be well to take cognizance of some discrepancies from this tradition and to show the importance of these discrepancies insofar as the cross-cultural study of achievement is concerned.

First, it may be noted that by reducing achievement motivation to more or less simple behavioral terms, some of the more attractive, imaginative, and exciting facets of achievement theory have been lost. Operationally defined and situationally limited, persistence, choice, and performance patterns are hardly as fascinating as McClelland's (1961) ubiquitous "Spirit of Hermes." But there are some distinct advantages in backing away from a more wholistic, comprehensive, and also imaginative approach to certain more limited but manageable specifications. Such specification more readily allows for the close situational analysis of the contexts that can and do elicit achievement behavior. It is, further, of special importance to the practitioner who is in the business of creating achievement on the spot. Perhaps of greater importance and interest is the fact that in defining motivation in this manner it has been defined as a phenomenon extant among all peoples and groups. Persistence, choice, and variation in performance are certainly not the sole property of persons in any given culture; they are universal behavioral patterns. Similarly, the achievement-defining conditions stated above can likewise be found in all cultures. Achievement motivation, as here defined, is assumed to be universal. Moreover, there is no necessary reason to believe that it exists to a greater or lesser degree in one or another culture. There is reason to suspect that it may well be elicited by different contexts and directed to different ends. In any case, this definition of achievement motivation seems to do more than shuffle concepts around. It establishes an entirely different orientation toward cross-cultural research.

Strategies in Predicting Achievement Motivation

STRATEGY 1: $C \longrightarrow P \longrightarrow M$

The first strategy relates to the role of "personality" in motivation. Since different cultures do provide different contexts for social learning, it is likely that members of these cultures will hold

varying orientations toward achievement and that such orientations will determine when and how achievement motivation will be exhibited. However, several questions must necessarily be raised regarding the use of this strategy.

First, it may be noted that the achievement of cross-cultural comparability in personality assessment is no mean problem. This is no less true in the case of the fantasy-based measures that have become the mainstay of achievement motivation methodology. Aside from reservations that one might have about such measures generally (see Entwisle, 1972; Klinger, 1966, 1967; Weinstein, 1969), cross-cultural research compounds the problem. It is difficult, if not impossible, to make the cues used to elicit achievement imagery comparable across cultures. For example, are measures of achievement motivation based on fantasy responses to pictures designed for blacks (see Mingione, 1965, 1968) equivalent to those normally used with whites? Are pictorial cues suggesting males in an achievement context fair to females, or vice versa? (See, e.g., French & Lesser 1964; Lesser, Krawitz, & Packard, 1963.) And will such differences between sexes in any given culture exist in a comparable fashion between cultures? (See Heckhausen, 1967, p. 17 ff.) Pictures are a part of a culture as much as words (see Cole, 1972; Maehr, 1974; Segall, Campbell, & Herskovits, 1960). Recognizing such difficulties, some researchers (e.g., Horner, 1968) have employed verbal cues in eliciting achievement imagery. However this may reduce the comparability problem in cross-cultural research, it hardly disposes of it altogether.

Related to such assessment problems, there is a more basic conceptual problem. McClelland, like others concerned with personality and achievement, has given minimal attention to distinctions between the motive to achieve and the ways in which this motive might be actualized—dependent on culturally approved means and ends. Rather, the achievement motivation literature emphasizes that achievement depends on a generalized desire to achieve and, at least by implication, minimizes the importance of also knowing and valuing the appropriate instrumental behaviors. Culturally derived beliefs about ends (terminal values) and means (instrumental values) typically play little or no significant role in conceptualizing achievement motivation. Moreover, the personal desire or inclination to achieve is usually confounded with the goal to achieve in such a way that little consideration is

given to the possibility that one might exhibit all or most of the basic behavior supposedly characteristic of highly motivated persons, only directed to different ends—ends that are appropriate in one, but not another, culture.

The problem is not unimportant as far as a cross-cultural study of achievement is concerned, and it is critical, for example, to an educationist concerned with so-called "culturally deprived" children. According to the usual way of conceptualizing and assessing achievement motivation (n Ach), the lower-class black child comes out on the short end. Those who have read about and conducted game-like experiments purporting to provide some validation for the construct n Ach and have also observed so-called "disadvantaged" children at play or at work in their own settings may be a bit suspicious here. There seems to be a lot of n Ach behavior on basketball courts in black ghettos, even though the participants are presumably low in this particular personality trait. The counterargument, of course, is that such instances are probably not sufficiently general across a wide variety of situations and the high n Ach person is one who exhibits such behavior typically and characteristically, not just in a few specific and identifiable instances (see McClelland et al., 1953). But the problem may actually be that current assessment procedures are so culture bound that they only sample instances of achievement motivation associated with a given culture. Granted that such assessment may provide the best basis for predicting achievement in this culture, is it a fitting basis for assuming that the individual from an alternate culture has a limited will or desire to achieve?

Additionally, Strategy 1 poses problems insofar as intervention is concerned. Essentially, this strategy implies that achievement motivation can be increased only as the personal history of the individual is in some sense reversed: Changes in achievement motivation involve personality change. In order to increase the achievement motivation of the ghetto black, the Mexican-American, or the Iranian peasant, a kind of psychotherapy is necessitated in which a basic personality transformation can occur. While it has been demonstrated that this type of intervention is possible (Alschuler, Tabor, & McIntyre, 1970; McClelland & Winter, 1969), it is also problematic. One might, then, question just how practicable this intervention strategy actually is. Certainly, there have been and there will continue to be instances when se-

lected individuals will submit themselves to the rigors of such personality change, but what suggestions does it hold for the more typical situation? The teacher in an inner-city high school or the employer of so-called disadvantaged persons will likely derive little but a fatalistic outlook from such suggestions, for after all, what can they do about lack of motivation when it is simply in the nature of the person?

Finally, then, this strategy must be considered in developing a complete understanding of achievement motivation. It can hardly be denied that social learning plays some role in creating personal dispositions. However, just as clearly, the time is ripe for a certain redirecting of activity even when operating in a culture and personality mode. In addition to taking value assessment more seriously, traditional measures of achievement motivation must be viewed more critically. Conceivably, it would be profitable to define personality more explicitly in terms of the culture in which the person exists. Possibly also, the most cross-culturally valid definition of high- and low-achievement-motivated persons must be based on the structure of social meanings an individual holds—the subjective side of culture (cf. Saral & Crotts, 1971).

STRATEGY 2: S —————> (P) —————> M

There is an extensive literature that deals with the role of situations in affecting achievement motivation. By and large, this literature argues strongly for the conclusion that situational variables play a major, and in many cases *the* major, role in determining behavioral patterns that are labeled achievement motivation. Since different cultures characteristically create different situations as well as adapt to general situations in idiosyncratic ways, arguments underscoring the importance of situational variables increase in importance as one attempts cross-cultural study. This literature is worthy of closer scrutiny than it has sometimes had by those concerned with the nature and sociocultural origins of achievement motivation. Although it is impossible at this point to incorporate the many and diverse findings into a single, nicely integrated, theoretical statement, it is possible to identify dimensions of situations that seem to be critical in determining achievement motivation.

The normative dimension. At the outset it should be noted that an individual does not achieve in a social vacuum. He achieves as a member of a social group, and in such behavior as choosing

and persisting he is influenced by the guidelines, expectations, and values of the groups that are significant to him. There is much that has been said on this point, but less has been done in systematically analyzing such normative influences on motivational behavior. Recently, however, several lines of research have proved particularly interesting. The first line of research has involved a role analysis of achievement behavior. Klinger and McNelley (1969) reviewed considerable literature that supports the hypothesis that role changes and movement in the status system affect achievement motivation. A notable study here is one conducted by Zander and Forward (1968), in which subjects identified as high and low in *n* Ach following usual procedures assumed leader and follower roles in a three-person group performance experiment. While in the follower position, high and low *n* Ach subjects did differ in the behavior they exhibited—much along lines that one would predict on the basis of the person-based achievement motivation theory associated with McClelland's group. However, when placed in a leadership role, both high and low *n* Ach subjects exhibited high *n* Ach behavior. What is particularly intriguing about this is that such a momentary switch in social roles can have such immediate and direct effects on motivational behavior—motivational behavior that is typically attributed to enduring personal disposition.

Recently, Stuempfig (1973) established a research paradigm for systematically analyzing the effects of status changes on achievement motivation. The point in question here is hardly trivial insofar as the practitioner-teacher, employer, or recreational leader is concerned. At the least it may suggest how variable and flexible these presumed personality characteristics may be (see Hunt, 1969). It may also suggest that, in fact, these basic achievement behaviors are routines or behavioral patterns which are normally developed in most persons through the course of socialization, ready to be elicited under the "right conditions." Conceivably, then, achievement motivation is universal, perhaps also evenly distributed, and it is only a question of establishing the appropriate cues or context for eliciting these behaviors.

For the educator, a second line of research is of special interest—that concerned with so-called "teacher expectancy effects" (Rosenthal & Jacobson, 1968). Briefly reviewed, there is a growing amount of evidence that teachers "slot" children into certain categories, much as people filling differ-

ent social roles are slotted. Once slotted, a child is expected to perform in one or another way and does—fulfilling, as it were, a kind of prophecy. Recent work by Rubovits and Maehr (1971, 1973) has demonstrated how teachers behave toward differentially slotted students. While the amount of feedback distributed among children labeled “gifted” or “average” did not vary, the quality of feedback did. “Gifted” children were given the approval and praise which in other contexts had been shown to increase self-regard (Haas & Maehr, 1965; Ludwig & Maehr, 1967; Maehr, Mensing, & Nafzger, 1962), perhaps by changing attributional patterns (Dweck & Reppucci, 1973; Weiner & Kukla, 1970). In any case, the expectations that elicit conformity to roles and norms indirectly affect achievement by eventuating in the approval/disapproval patterns that create the persistence, choice, and performance patterns that give rise to accomplishment.

A third line of research focuses more directly on the cognitive aspects of roles and norms. One not only follows a given role pattern because of the prospect of certain rewards or sanctions but also follows those patterns of which he has some knowledge and which have salience within the cultural context he knows. The analysis of “subjective culture” (Triandis et al., 1972) provides a possible entrée in identifying which behavioral patterns make sense to a member of a given culture. Persistence on the basketball court may be the perceived antecedent to success and achievement in one culture, but not in another. Whether or not an individual has knowledge of “what really leads to what” in an objective sense, he will probably only receive encouragement from significant others if and when the appropriate antecedent-consequent patterns are held. Knowledge and valuing of appropriate patterns are critical in establishing achievement patterns.

Other lines of research could be cited in illustrating the importance of culturally established roles and norms in affecting what is ultimately labeled as achievement motivation, but perhaps the point has already been made. In one sense, it is an obvious point. But obvious as it is, it is surprising that it is not taken more seriously and employed more pervasively in the systematic analysis of achievement motivation.

Locus of control dimension. A second dimension that emerges in the analysis of achievement situations might be termed the *locus of control dimension*.

The previously stated definition of achievement clearly assumes that the achievement context must permit the achiever to be, in some sense, in control of the situation and responsible for the outcome. However, the fact remains that situations can and do vary in the degree to which such control is transferred to the achiever. Achievers may, in varying degrees, be engaging in a behavior of their own choosing, pursued for ends they themselves designate.

Currently, there is considerable interest in the role of locus of control and attributional processes in achievement motivation (Crandall & Battle, 1970; Crandall, Katkovsky, & Preston, 1960; Gurin, Gurin, Lao, & Beattie, 1969; Weiner, 1972a, 1972b, 1974; Weiner & Kukla, 1970; Weiner, Heckhausen, Meyer, & Cook, 1972; Weiner et al., 1971). This work has progressed beyond personality analysis to show how certain contextual conditions create the “illusion” of control (Lefcourt, 1973) and thereby drastically affect achievement motivation. DeCharms (1968, 1972) has shown that those contextual conditions that communicate to persons that they are “origins” rather than “pawns” will increase their achievement motivation. Similarly, Maehr (1967, 1969; Maehr & Stallings, 1972) has pointed out that freedom from external control in learning may encourage a continuing interest and a greater willingness to engage in challenging tasks.

Quite obviously, locus of control is a critical contextual variable. It seems to have some definite and specific effects on how persons view their capacity to achieve as well as having observable effects on achievement behavior per se.

Interpersonal dimension. A third dimension to be considered in the analysis of achievement contexts deals with interpersonal variables. In this regard, one should first of all take cognizance of the considerable literature on the “quality” of feedback on performance. For example, it seems that whether an individual is simply provided information on his performance or given personal feedback from a significant other may make a difference. Moreover, the effects of personal feedback are further affected by the relationship that the performer has with the significant other (Katz, Henchy, & Allen, 1968; Stuempfig & Maehr, 1970). Persistence, choice patterns, and performance seem to be significantly influenced by the way evaluative information is communicated to the achiever. Such information can be made to be or in fact is a social

event having varying influence, dependent on its meaning to the performer.

There is, however, another consideration to be noted: the organization of achievement in an interpersonal context. Achievement situations can be defined as "self-competitive" or "other competitive" (Maehr & Sjogren, 1971). On the one hand, the standard of excellence imposed on or associated with the situation may be socially normative, involving comparison or competition with others. On the other hand, it may be structured so as to involve comparison or competition with idiosyncratically defined standards. And, of course, there are a variety of ways to subdivide further, but the point to be stressed is that social competition may be more or less involved in any given achievement situation. This possibility has been insufficiently considered in the achievement literature. Atkinson's (Atkinson & Feather, 1966) model of achievement motivation seems to be primarily, if not exclusively, valid given a socially competitive situation. It was structured in terms of socially competitive games and may be restricted to such contexts insofar as its explanatory and predictive value is concerned (Maehr & Sjogren, 1971). Although Veroff (1969) made an important attempt to consider the role of social competition developmentally, little attempt has been made to understand self- and socially competitive patterns within a broad array of cultural contexts. While the Navajo child may not exhibit motivation to achieve in a socially competitive context, will he perhaps demonstrate such motivation when interpersonal conditions are so designed to fit more appropriately with patterns acceptable within his culture?

Task dimensions. Finally, one must take into account various task factors. Not only does this involve a consideration of levels of difficulty, already thoroughly dealt with in the achievement literature (e.g., Atkinson & Feather, 1966) but also the identification of "intrinsic" task interest (Day & Berlyne, 1971). Above and beyond that, however, it is clear that there is a necessity to attempt to scale tasks in terms of some sort of cultural relevance dimension. Such scaling would certainly involve a consideration of facets of achievement associated with several of the previously designated dimensions. Thus, it would seem most logical to consider tasks in terms of the normative factors previously mentioned. To what extent is a given task perceived as an appropriate antecedent to a desired consequent? As a parent, I am readily

aware of the fact that my sons exhibit considerable motivation to read above and beyond the requirements of the context in which reading is formally an achievement task. I am also aware that they may not be typical of all children. Reading has a special place in a professor's family; some other behaviors do not. It is, therefore, surprising only when my children refuse to read, not when they choose to do it. This is a homey and oversimplified example of cultural relevance of a task, but perhaps it makes the point.

Summary. Situations do determine that behavior which is presumed to be indicative of achievement motivation. Moreover, a situational and contextual analysis of achievement motivation is likely to provide a fuller understanding of achievement-related behavior as it varies from culture to culture. Without such situational analysis it is all too easy to assume "motivational inferiority" in the case of those who achieve under different times and circumstances than we.

STRATEGY 3: C \longrightarrow P \longleftrightarrow S = M

The third strategy in some sense represents the most sophisticated analysis of achievement motivation. This strategy specifically identifies both personality and situation as simultaneously critical variables. Taking their cue from Lewin, a number of $P \times S$ models of achievement motivation have emerged. Perhaps the most prominent and highly developed of these is the one proposed by Atkinson (Atkinson & Feather, 1966). Although the model initially seemed limited in terms of its applicability to a variety of situations and cultural contexts, recent adjustments (e.g., Atkinson & Raynor, 1974) have improved matters. Without delving into the specific merits or problems of the Atkinson model per se, consider the workability of the general $P \times S$ strategy implicit in this approach as it relates to the analysis of behavior in different cultural contexts.²

Basically, this strategy puts considerable emphasis on how certain situational conditions will elicit responses dependent on previously acquired predispositions. Anyone who has conducted research on the influence of situational factors on motivation has probably noted the existence of individual

² Critical analysis and reviews are sufficiently available on this point. See, for example, Maehr and Sjogren (1971) and Weiner (1972).

differences in response to the treatments (e.g., Maehr, 1974; Maehr & Stallings, 1972). This in itself argues for a consideration of a $P \times S$ interaction within any complete statement of motivational theory. But there is a special reason for giving consideration to this strategy in varying cultural contexts, especially if one is ultimately interested in practical questions. Taking this strategy into the practical realm suggests a matching models approach (e.g., see Hunt, 1971; Stuempfig, in press) in eliciting desired behavior. If, for example, one wishes to design a recreational program for children, this strategy suggests that one must know something about the predispositions of these children. Simultaneously, something must be known about the effects of certain situations on these children in order that situation and person may be matched to achieve desired ends. As an example, some children may be motivated by highly structured play, by challenging tasks, or by competition with others, and others may not; the trick is to find out who is motivated by what. Moving from one culture to another, this or that situation may elicit the desired behavior depending on the culturally defined predispositions of the children in question.

In an important sense, this third strategy actually represents the ultimate goal of the search. Even in stressing the importance of Strategy 2 it has been implied that the ultimate fruition would be the identification of situations that work for different persons, whether persons are identified on the basis of personality tests or ethnography. However, some of the available $P \times S$ models are manifestly ineffective for these purposes, precisely because concepts of both situation and person have developed and evolved in very limited cultural contexts. The P variable in Atkinson's model, for example, is subject to most of the criticisms made in focusing on McClelland in discussing Strategy 1. The two components of P , "tendency to approach success" and "tendency to avoid failure," are both rooted in and directed to achievement as it occurs in a specific culture. *Tendency to approach success* is assumed to be adequately indicated by the fantasy-based measures of achievement motivation discussed previously; *tendency to avoid failure* is presumably indicated by the Test Anxiety Questionnaire, an instrument manifestly focused on a very specific achievement behavior as it occurs in certain cultural contexts. Similarly, the situational variables employed within the model represent a

limited sampling of the dimensions of situations. Probability of success and directly related incentive values are given primary, if not exclusive, consideration. Although some attempt has been made to incorporate other variables such as locus of control (e.g., see Feather, 1967) and instrumental value of the task (Raynor, 1969, 1970), the burden of a more expanded situational analysis of achievement has certainly not been relieved. It is questionable, then, whether it is indeed profitable to operate within the context of this model in the case of different cultural groups, perhaps tacking on a new variable (locus of control, fear of success, etc.) here or there as the results seem to suggest. Even with the ultimate goal of achieving a working $P \times S$ model for research, the present stage of knowledge regarding culture and person demands a fresh look at person and situation at those times and in those places in which achievement motivation, as a more cross-culturally general phenomenon, occurs.

Toward the Naturalistic Study of Achievement Motivation

The thrust of the arguments thus far culminates in a plea for a "culturally based" (Brown et al., 1973) conception of achievement motivation derived from a contextual and situational analysis of achievement behavior. Quite possibly, they further suggest that we complement our experimentation with the naturalistic study of achievement motivation.

The argument for a situational analysis of achievement motivation has thus far been primarily buttressed by references to research conducted within the realm of experimental social psychology. A more telling argument could perhaps be made on the basis of naturalistic studies. As Labov (1970) pointed out, it is easy enough to assume that the black, the Chicano, or some other minority group member is deficient in language development if one only considers classroom conditions or observes these individuals in the context of a standard psychological experiment. But the highly developed language behavior that is not exhibited in the classroom may be elicited in the street, in the living room, or in the pool hall. Similarly, the uneducated African cowherd may exhibit learning and memory deficits on the standard tasks of Euro-American psychologists. However, in some contexts he possesses a remarkable memory for certain facts and feats, recalling readily the intricate details of cattle

transactions over many years. And if stimuli are presented in ways and contexts that are compatible with his culture, one finds little evidence of impoverished learning capacity (Cole, 1972). Quite possibly, similar principles are also operative in the case of motivational behavior. The achievement motivation that is not found among the so-called culturally disadvantaged (Rosen, 1959) may not have been found because it was not sought in the right places.

In the first instance this conclusion is a logical development from the previous arguments in relation to the importance of situations in determining achievement motivation. It may be more than that. Putting the issue this way may suggest that we employ a research methodology different than we have typically employed in the study of motivation. In outline form, that methodology implies that we, first of all, identify settings in which achievement motivation, as defined previously, occurs or does not occur in various cultures and then proceed to characterize the nature of these settings. Additionally, it is assumed that certain choice, persistence, and performance patterns, which may be labeled achievement motivation, will occur in all cultures. Furthermore, it is assumed that naturalistic observation will readily reveal instances when these patterns are maximally and minimally exhibited in any given culture.

Much of the research that attempts to understand the motivational patterns of ethnic and cultural groups involves placing children in a "middle-class-biased" performance setting and then observing behavior. If this strategy is undertaken with the conscious goal of determining how one gets children to adapt to middle-class-biased performance settings, it makes some sense. If, however, one is willing to accept the notion that performance settings must in some sense adapt to children, it makes less sense. Indeed, given this latter inclination, it may make more sense to find out when children "turn on" and replicate those situations within the curriculum or program. At the very least, this procedure might provide a more culturally based conception of motivation. It would probably also yield the conclusion that achievement, as here defined, is not absent in certain cultural groups. It might even force the conclusion that it is equally present in all groups, although it is elicited in different ways and to different ends. But of greatest importance, it might provide fresh insight into the design of intervention strategies to

the effect that in creating motivation sometimes it is better and more convenient to change the situation rather than the person.

Perhaps, then, we would do well to pursue an ethnographic approach to the study of motivation, particularly in work with varied cultural groups. Not that this approach should be pursued exclusively, nor should it be pursued in an atheoretical manner. As a matter of fact, it could quite appropriately be pursued in terms of the social-psychological dimensions of achievement behavior that were suggested earlier. The important principle is that achievement and achievement motivation must be understood in terms of the sociocultural context in which they are found, as well as in terms of generalized descriptions of achieving norms or abstract constructions of psychological processes.

Conclusion

Serious problems exist with what might be called a "dynamic analysis" of achievement motivation. A focus on the inner state of the person—his achievement *need*—has typically eventuated in an ethnocentric construction of the nature of things. While for certain purposes such ethnocentrism may have its place, it also has its distinct limitations. What is needed is a framework within which culturally based conceptions of achievement motivation can arise. This need not represent a total rejection of theory for simplistic empiricism. It does involve a clearer specification of the object of study and more serious devotion to the analysis of situations, contexts, places, and events in which this object of study is to be found. In this we may do well to follow the lead of Michael Cole and others (Cole, Gay, Glick, & Sharp, 1971; Cole & Scribner, 1974) who have created an experimental anthropology of cognition and create an experimental anthropology of motivation. At the very least, it is clear that if work is to be carried out effectively with persons of varied cultural backgrounds, it is well to know more than how they relate to the "Protestant ethic."

Scientific Awards Announcement

The Committee on Scientific Awards is accepting nominations for its award program. The Committee selects up to three persons as recipients of the Distinguished Scientific Contribution Award who, in its opinion, have made the most distinguished theoretical or empirical contributions to scientific psychology in recent years.

A new award, the Distinguished Contribution for Applications in Psychology, has been authorized by the Board of Directors and will be given for the third time this year. This is presented to an individual who, in the Committee's opinion, has engaged in a program of research which is systematic and applied in character.

The awards are subject to the following limitations: (a) members of the Committee, former recipients of the awards, the President and the President-elect of the APA shall be ineligible. (b) The Committee shall seek diversity in selecting recipients, avoiding as far as possible the selection of more than one person representing a specialized topic, a specific material, a given method, or a particular application.

Names and appropriate information which will guide the Committee on Scientific Awards in conducting an intensive career review and evaluation should be forwarded to Office of Scientific Affairs, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036. *Deadline for nominations is January 15, 1975.*

Progress in Psychology: 1903–1907

WILSE B. WEBB *University of Florida*¹

Beginning with the February 1904 issue of the *Psychological Bulletin*, the journal's editor, Edward Franklin Buchner, of the University of Alabama, established a "department" in that journal called "Psychological Progress." For the next five years he published a review of the preceding year's psychological panorama (Buchner, 1904, 1905, 1906, 1907, 1908).

Fired with enthusiasm for his task, he declared in his first article that

particularly in the domain of science, readjustment, as demanded by any given situation, is the *sine qua non* of progress. . . . Effective readjustment in the interest of what ought to be can only be made in the light of what has been. Prevision requires revision; and revision requires retrospection [p. 57].

This article on Buchner's five reviews of psychology from 1903 through 1907 has far more modest goals. Its primary purpose is, to modify a contemporary phrase, "to tell it like it was"; to convey some sense of psychology 70 years ago. In doing this I hope that a retrospective view may demonstrate that our "progress," from then to now, may well fit another phrase from Buchner's introduction: "Progress may thus come to be actually a direct advance, a tangential detour, or even a definite retreat [p. 57]." I would add, "or perhaps only an appearance of progress."

I can find no simple way to summarize Buchner's nearly 50 pages of tightly packed summaries. I will first present an introductory quantitative analysis, based on data drawn from the articles, about the number of psychologists and their written record in order to set the stage for the subsequent statements about prominent people and issues of those times.

The Data

In his 1907 article, Buchner compared the production of psychological doctorates in American uni-

versities over the preceding nine years with other scientific disciplines: chemistry, 282 doctorates; physics, 133; zoology, 128; psychology, 124 (an average of about 12 per year). In the following year he reported a slight decrease in psychological doctorates to 10. For comparative purposes, according to 1973 National Research Council data, the universities of the United States produced the following number of doctorates in 1972 in the categories cited: chemistry, 2,204 doctorates; physics, 1,627; zoology, 354; psychology, 2,116. Hence, in relation to these fields, the number of psychology PhDs rose from 19% to 34% of the total. Buchner (1907) also reported that 4.85% of the men listed in American Men of Science for 1906 were identified as psychologists.

A second set of data reflect the interests of psychologists of that time through their publications. The *Psychological Index*, a predecessor of *Psychological Abstracts*, listed and categorized yearly the psychological literature being published worldwide. Buchner reported on these psychological publications for the years 1903 through 1906. The findings are shown in Table 1.

There is an uneven upward trend in the number of publications, with about one-third more articles in 1906 (3,145) than in 1903 (2,122). For comparative purposes we should note that two issues of *Psychological Abstracts* (1971 and 1972) contained 22,982 articles and 24,326 articles, respectively.

The last five categories of publication varied less than 1% across the four years. There are, however, informative shifts in the first five categories. I would roughly translate these categories as follows: "Higher manifestations of the mind [sic]" refers primarily to philosophical considerations. In fact, in the 1906 rubric, this category was specifically redesignated as "philosophical implications of psychology." The category "genetics, individual and social psychology" combines interests in developmental, individual differences, and social psychology and substantively reflects the interests of "functional," "dynamic," and applied psychology.

¹ Requests for reprints should be sent to Wilse B. Webb, Department of Psychology, University of Florida, Gainesville, Florida, 32611.

TABLE 1

Percentages of the Distribution of Literature in the Psychological Index

Year							
1903		1904		1905		1906	
Topic	%	Topic	%	Topic	%	Topic	%
I	18	V	21	I	18	V	19
II	18	II	18	V	17	III	18
III	17	III	17	III	17	I	17
IV	13	I	13	II	16	II	12
V	10	IV	10	IV	10	IV	11
VI	8	VI	8	VI	8	VI	9
VII	6	VIII	6	VIII	5	VIII	5
VIII	5	VII	5	VII	5	VII	5
IX	3	IX	3	IX	3	IX	2
X	2	X	2	X	1	X	2
Total N	2,122		3,445		2,727		3,145

Note. I = higher manifestation of mind; II = genetics, individual and social psychology; III = sensation; IV = anatomy and physiology of the nervous system; V = sleep, trance, and pathology; VI = general; VII = cognition; VIII = conation and movement; IX = characters of consciousness; X = affection.

The categories "sensation," "anatomy and physiology of the nervous system," and "sleep, trance, and pathology," respectively, indicate primary interests in psychophysics, physiological psychology, and abnormal or "clinical" psychology.

Accepting these interpretations, the figures suggest a steady interest in psychophysics (a range from 17% to 18%), a relatively steady interest in physiological problems (a range from 13% to 10%), and a declining interest in genetics, individual differences, and social psychology (a range from 18% to 12%). The major fluctuations occur in the philosophical and clinical categories and reflect the ferment of the times (see below). Philosophical articles varied in rank from 1 to 4 and in percentage from 18% to 14% of the writings of that period. The clinical category rose from 10% and fifth rank in 1903 to 21% and first rank in 1904 and maintained its first or second rank in the following two years.

People, Issues, and Events

The following section includes a very select series of extracts from Buchner's five articles on certain key persons, issues, and events. The basis and bias of the selections have been an emphasis on individuals and trends that evoked, in this reviewer, a resonant contemporary response. There has been an almost complete omission of the reports of sub-

stantive experimental contributions. As a result, there have been omissions that different reviewers of different backgrounds and interests would have certainly included.

The extent of this bias and selectivity can be best shown by noting, for example, that the review of 1905 (Buchner, 1906) contained some 50 individual names. Of these 50 persons, only 7 are specifically referred to in the body of this article. Two paragraphs are devoted to aesthetics (Volkelt, Lipps, and Witasek) and two to the psychology of religion (Vorbodt and King). Almost a page is given to the psychology of affection or feelings (Hall, Johnson, Ribot, Geiger, Lipps, Wundt, and Baldwin). One and one-half pages report on the specific experiments on vision and visual movements by Wallin, Baird, Judd, McAllister, Steele, Stratton, Dodge, Smith, and Moore. None of this rich trove is reflected below. Thus particularized interests of many readers are omitted. I can commend the basic articles to almost any special interests of today. I suspect that most "modern" concerns can find nascent or developed reflections of those interests in these five reviews.

ON BINET AND INTELLIGENCE TESTS

That the psychological world is not at peace with itself on this question of method also appears from a contribution of Binet to individual and child psychology [*L'étude expérimentale de l'intelligence*, 1903]. His study of young members of his family by a combination of "tests" and introspection was primarily designed as a means of heralding "a new movement" in method. This is to supersede the "Wundtian epoch," which has been physiological and statistical. In his reaction against persistent quantitative ideals, Binet demands that we pay attention to the individual traits of experimental subjects, and that study be made of the higher mental processes and not of the lower elements. Binet's position seems to be national. Shall France give us a new method of psychologizing? Toulouse, Vachide and Pieron, in presenting the result of several years' work, from their own point of view, consider only the technique of "tests" by which the mental qualities of an individual are measured. Independently of practically all previous work done on "tests," they attempt to formulate a system of psychological tests which are to be standardized by pointing out the exactly reproducible conditions in measuring subjects [Buchner, 1906, p. 128].

ON TITCHENER

Neither of the above [referring to Binet] is to be compared with the permanent addition Titchener continues to make to the finished literature of experimentation as a definite and well-established mode of approach to psychological problems. . . . The best symptom of progress in the field open to experimentation is to be found in Professor Titchener's timely St. Louis address [*American*

Journal of Psychology, 1905] which became available near the beginning of the year. Looking both backward and forward, this unusually excellent review of progress, trenchantly stated in terms of present experimental ignorance, will remain for some time to come an open guide to our laboratories. His earnest plea for more thorough testing of available methods and renewed research over much of the old ground is already being realized [Buchner, 1906, pp. 128-129].

The contributive systematic work [of] Professor Titchener continues in the better pedagogy of experimentation [Buchner, 1905, p. 95].

Surprisingly, these appear to be the only references to Titchener during the five years.

ON WILLIAM JAMES

The strong influence of William James is seen in his appearance in all four years of substantive review (Buchner, 1904, 1905, 1906, 1907). He is described by Buchner as "our psychological Moses." In "Psychological Progress in 1904," Buchner (1905) reported James confessing that

he has been uneasy, as early "as twenty years ago," about consciousness as a thing, a biographical item which must hereafter give permanent and perhaps reversed coloring to the two magnificent volumes which gave us our great English classic in 1890 [p. 91].

In "Psychological Progress in 1905," Buchner (1906) continued to worry about James, who "advised us that consciousness does not exist [p. 127]" and also reported his inaugurating the Department of Philosophy at Leland Stanford Junior University. "Psychological Progress in 1906" reported three experiments testing the James-Lange theory of emotions (Buchner, 1907). In "Psychological Progress in 1907," reporting on the influence of pragmatism in psychology, Buchner (1908) said, "One's disappointment with this assiduously prosecuted new tendency is keen when James . . . carries the systematization no farther than to leave it 'a mere mode of approach' [p. 7]."

Of particular interest is Buchner's (1908) comment on James's Presidential Address to the American Philosophical Association in which he contended that

there is more of man than ordinary experimental psychology reveals. In view of the fact that men constantly live inside their limits of power, it is proposed that new measurements of energy or will power be made in order to build up the practical pathway whereby men may live on higher levels [p. 9].

ON WUNDT

Clearly the thoughts and research of Wundt represented a prominent aspect of psychology during

this period. "Psychological Progress in 1904" (Buchner, 1905) reported a questioning of Wundt's tridimensional analysis of the psychology of feeling into pleasure-displeasure, excitement-depression, and tension-relief. "Psychological Progress in 1905" (Buchner, 1906) reported on Wundt's account of the development of modern psychology in which he "finds the unity of Hegelian philosophy to be the inspiring seed of the last century's developments [p. 125]" and refers to Wundt's well-known positions on the psychology of feelings and his demands that "feelings be regarded both subjectively and objectively, in order that they may receive a treatment into elements and relations, much the same as sensations receive [p. 130]." "Psychological Progress in 1906" (Buchner, 1907) referred to Wundt's second volume of *Volker Psychologie* which

well indicates how the fields of anthropology and sociology may be reconstructed in the hands of a master in psychology. [In this book] primitive tendencies [in racial beginnings] . . . are viewed as on a level with the processes of perception in individual psychology. . . . Myth-making is identical with the process of sense-perception. . . . To the skeleton of this bold theory, flesh and blood are given by his adaptation of *Einfühlung*—the current esthetic theory [pp. 5-6].

ON HERBERT SPENCER

About two thirds of Buchner's (1904) first article is concerned with the contribution of Herbert Spencer to psychology's role as an independent science. This emphasis was perhaps accentuated by Spencer's death the year before:

The death of Herbert Spencer . . . brought to a close one of the most important movements in modern psychology [p. 59]. . . . [The *Principles of Psychology* (1855)] became and remained one of the dominant forces in shaping psychological theory, often negatively . . . [p. 60].

Psychology was developed by Spencer, not for its own sake, but as a means of exploiting the evolutionary hypothesis . . . [p. 61].

Psychology was defined by Spencer as follows:

Under its subjective aspect, psychology is a totally unique science, independent of, and antithetically opposed to, all other sciences whatever. The thoughts and feelings which constitute a consciousness, and are absolutely inaccessible to any but the possessor of that consciousness, form an existence that has no place among the existences with which the rest of the sciences deal [p. 62].

[For Spencer], "the data" of psychology . . . are supplied by biology through its knowledge of nerve structures and function. . . . The prime duty of psychology is to determine the definite relations between the two series of physical and mental phenomena. . . . The evolution of the mind [feelings and relation between feelings] is the progressive "adjustments of internal relations to external

relations"—the quality which distinguishes the truths of psychology from those of physiology [p. 62].

Buchner concluded by saying,

It is impossible at this time to make a tabular exhibit of specific influences emanating from this strained and partial theory of mind. The movement is closed; but the spirit of its motif lives stronger than ever in the genetic method and conception to which it gave such a wide preparation [p. 64].

Other Prominent Names and Ideas

Clearly, Mark Baldwin and James Cattell were important influences of the time. Both men appeared in all of the reports from 1905 to 1908. Each year there was reference to Baldwin's "consciously genetic method through the entire structure of cognition from the simplest to the most developed mode." Cattell's role appears to be that of spreading the dimensional directions of psychology:

He contended that psychology is not definable. The logical lack of determinability of the science, however, does not prevent there being 'psychologists.' Whatever these students study, *qua* psychologists, constitutes the field belonging to the science . . . Professor Cattell thus holds forth the promise of larger things for the future, and in doing so he but reaffirms the recurrent attitudes which during two decades have been clearing more ground for the advent of the psychologists [Buchner, 1906, p. 127].

There are two interesting references to Thorndike. One (Buchner, 1906) refers to his text *Elements of Psychology*, which emphasizes both the "descriptive" and the "dynamic" sides of psychological problems. At another point (Buchner, 1905) Thorndike is cited as calling for the

eschewing [of] speculative opinion . . . for the employment of the methods of "exact" science, a call which, as followed by himself, amounts to doing all the work over again. In fact this countertendency is quite as revolutionary as that noted above [the distinction between introspection and observation as modes of approach] [p. 93].

Other individuals mentioned several times include Dewey, Calkins, Judd, Stratton, and Angell. There are no references to Freud.

ON COMPARATIVE PSYCHOLOGY

There are two reviews of comparative psychology (Buchner, 1906, 1908):

Comparative psychology is showing signs of increasing healthfulness. . . . It has already made a wide departure from the old-time observation of the naturalist, and is growing more and more insistent upon facts secured from controlled situations. While passing through the elementary stage of determining the sensory and motor elements in the mental life of animals, this branch of psychology is happily young and plastic enough to reap all benefit

from the development of functionalism. The publication of the first volume in the "Animal Behavior Series" by Yerkes, and Watson's call for a new journal to be devoted to comparative psychology are unmistakable evidences of the rapid development in this field [Buchner, 1908, p. 9].

This is followed by a reference to Watson's doctoral dissertation, published in the *Psychological Review* of 1907.

ON SOCIAL PSYCHOLOGY

The status and thrust of social psychology during this period seem far from clear. Buchner (1905) said that

among those psychologists who are more inclined to social phenomena, there is a marked tendency to agree that a so-called "social mind" does not exist, and that social phenomena do not exist apart from the individual. Social psychology now tends to devote itself to a study of the individual mind in so far as it presents what is known as "group consciousness." When this theory is carried over to the child or to the race, social psychology readily falls into the keeping of a genetic psychology. . . . There is a danger in a tendency of the systematic psychologists to play too freely into the hands of the social relationship for explanatory factors, as, for example, Royce . . . who interprets the development of reasoning as due solely to the socius. On the other hand, that there continues a steady widening of the psychological point of view, hesitating not before the needs of a cool dissection of our practical living, is evidenced by Veblen [The Theory of Business Enterprises] and Scott [The Theory of Advertising] [p. 96].

Buchner (1906) next noted:

That social psychology may come to include sociology in so far as the careful analyses of individuals in social relations is concerned, is a position which seems to be gaining ground. . . . Draghiscesco [contends] individual consciousness originates in social consciousness, and the psychology of the individual must turn away from a biological explanation of his experience. . . . Ross [presents a] balanced scheme for tracing out the ramifications of psychological interests in the different fields of human life. . . . A good illustration of basing social analyses on the import of psychological values is presented by Ghent, who interestingly traces the dominant economic character of society to mental development as an explanation of social changes [p. 131].

Again Buchner (1907) noted that

genetic and social psychology seem to be setting up a new house together. And, if one mistake not the signs of current discussions, the progeny will stand forth accredited to a new moral psychology, or the mental evolution of the moral attitude. There is already a large amount of raw material scattered in these provinces and in the adjacent region of religious psychology [p. 7].

ON CLINICAL PSYCHOLOGY

As noted in the discussion of Table 1, interest in "abnormal" psychology was exhibited by these

topics, proportionally occupying the first or second rank in publication rate for the years 1904, 1905, and 1906. There are other evidences of the strength of these interests. The *Journal of Abnormal Psychology* was founded in 1906 by Morton Prince and the Psychological Clinic in 1907 by Witmer. Buchner further noted (1908) "the application of 'the clinical' method . . . at the University of Pennsylvania and Harvard . . . [p. 11]." To this, Buchner added an interesting comment, "[This] may encourage the hope of seeing greater socioeconomic values placed upon the science in American community life [p. 11]." In this same year Buchner cited the English translation of *The Psychic Treatment of Nervous Disorders* by Dubois. He said, "This disciple of the school of Nancy supports the thesis that 'nervousness is a disease preëminently psychic, and psychic disease requires psychic treatment' [p. 9]."

There are two pertinent statements regarding psychology's relationship to psychiatry at this time. In 1905 Buchner said, "[There is] the steady reconstruction of psychiatry under the influence of a sound and generous psychology . . . [p. 97]." And in 1906 he stated that "psychiatrists are tending to show a greater reliance than formerly upon the value of exhaustive description and analysis of abnormal mental states for presenting the real problems of abnormal psychology . . . [p. 132]."

ON "FUNCTIONAL" PSYCHOLOGY

From Buchner's point of view, "functionalism" had won the day as a "philosophy" of psychology. Buchner (1905) first stated

that psychology is slowly but surely gaining a restoration of her once constructive influence upon a total view of experience. . . . This comes out unequivocally in the recent widespread acceptance and defense of the "functional" as over against the earlier "structural" view of the science [p. 92].

In "Psychological Progress in 1905," Buchner (1906), in speaking of Angell's book *Psychology: An Introductory Study of the Structure and Function of Human Consciousness*, stated that the structural and functional viewpoint which maintains "a strongly flavored biological point of view . . . tends to regard consciousness as merely one among many manifestations of organic life [p. 128]." In the next year Buchner (1907) noted:

The attitude of the psychologist towards his subject-matter seems to be less a question for debate or a theory of elaboration than formerly. In spite of the fact that

the functional point of view seems to have almost completely won out, there continue efforts to be even more precise in the application of criteria to consciousness [p. 3].

In "Psychological Progress in 1907," the influence of functionalism on increased attention given to the experimental investigation of the motor half of conscious processes was noted, and Buchner (1908) said,

This naturally brings one nearer the "practical" phases of daily experiences, and may result in removing the semi-popular objection to psychological experimentation that in view of the ingenuity and assiduity displayed the worth of the results thus far obtained has not been commensurate to the great labors [p. 5].

A Scattering of Pertinent Comments

How patiently experimental methods must proceed, and how meagre their results, in an analysis of the conditions of "learning," may be seen, for example, in Brown's study of the processes of addition, subtraction, multiplication and division. One of our great desiderata is an efficient psychology of learning . . . [Buchner, 1907, p. 5].

The attitude to Jennings is fruitfully different from that maintained by Pavlov in his recent Huxley Lecture, his contention being that physiology has been advancing by borrowed light, the explanatory ideas of psychology,—a source of "evil influences" [Buchner, 1907, p. 7].

In commenting on the *Dictionary of Philosophy in Psychology* by Rand, Buchner (1907) stated:

The literatures of these cognate fields are now within the grasp of the reader as never before, and the current additions to bibliography will tend to favor a better grade of scholarship in these departments of knowledge, and possibly check some of the rush "to print." . . . [however] The creation of new journals does not give much encouragement to such a hope [p. 8].

In speaking about terminology, Buchner (1905) stated:

We should be carried too far afield to specify . . . the renewed bearings of psychology upon those bantering philosophical novelties which are current under such terms as "radical empiricism," "humanism," "pragmatism," "instrumentalism" [p. 97]. [Or] It is a bit surprising to find a rising tide of dissatisfaction threatening to engulf some of the "older" (and almost consecrated) terms in psychology. The recent dispositions made of "consciousness" are closely followed by confessed willingness to see such terms as "feeling," "sensation," "perception," and others disappear entirely from the language of the student of human experience. Oddly enough, too, new terms are not at hand nor suggested to replace those now worn thread-bare by long usage. Might they have fallen into contempt by reason of too great familiarity? This tendency may be presaging the advent of the framer of the vocabulary of psychology for the new twentieth century [Buchner, 1907, pp. 1-2].

Apologia

As I review my review of these years I become aware of conveying poorly a most pervasive tone

and concern of the times: the unsettled and uncertain nature of the enterprise itself and the plaintive, persistent, and personal assaults on the associated issues of subject matter, method, and psychology's place in the systematic disciplines. Such issues as consciousness, mind, introspection, biologism, and application are all threaded throughout these summaries. In describing the 1905 International Congress of Psychology, Buchner (1906) said somewhat resignedly:

The geographical unity of time and space . . . must not be mistaken for the inner and progressive unity of a science. . . . There was no marked agreement; each continued to speak then just as he had hitherto thought in his individual capacity [p. 133].

Let me try to convey this tone by an extracted summary of Buchner's first two paragraphs from his final article in 1908:

Judged within the close range of its dying hours, the year 1907 does not seem to be conspicuous in the annual achievements of psychology. Sketching its story is a task not unlike the ancient one of making bricks without straw The angle of individual straws has shown the winds to have been blowing in all directions [p. 1].

That modern psychology is still an unsettled science is to be seen in the continued debate as to its real nature and the assumptions upon which its constructive activities are to be based. In his last work . . . Möbius reveals, as he thinks, the utter hopelessness of psychology in its struggle to become a science. . . . As much as to say that psychology is not "hopeless," Miss Calkins raises the query: Psychology: "What is It about?" In her partially published answer, the double demand is made that metaphysics be eliminated from psychology, and that the psychologist shall admit into his thinking the every-day

distinction between the psychical and the physical. . . . Stumpf has newly declared that the science is dealing with both mental contents and with mental functions. In a still more hopeful manner, Kirkpatrick would enrich the science's vocabulary while suggesting its need of a broader base. . . . The most systematic exposition, if not defense, of the rapidly spreading functional point of view that has yet been made appeared in Angell's presidential address. One would almost be led to believe that the long observed structural point of view was an abstraction and produced erroneous results . . . [pp. 1-2].

Envoi

There can be no summary of the summaries. I refrain from drawing the obvious contemporary parallels, detours, and retreats and leave these for each reader's amusement and bemusement. I end with a quotation from Witt Auden's *To Clio*, the Muse of History:

Madonna of silences, to whom we turn
When we have lost control
. . . forgive us our noises
And teach us our recollections. . . .

Reports of the Regional Associations for 1974

Beginning with the 1974 annual meetings, proceedings of the American Psychological Association and of the regional psychological associations will be published by and made available through the *JSAS Catalog of Selected Documents in Psychology*. The following proceedings are now available and can be ordered directly from the JSAS Office: Ms. No. 739, American Psychological Association, Proceedings of the Eighty-Second Annual Convention, 196 pages, \$8; Ms. No. 740, Southern Society for Philosophy and Psychology, Proceedings of the Sixty-Sixth Annual Meeting, 14 pages, \$2; Ms. No. 741, Eastern Psychological Association, Proceedings of the Forty-Fifth Annual Meeting, 88 pages, \$3; Ms. No. 742, Western Psychological Association, Proceedings of the Fifty-Fourth Annual Meeting, 60 pages, \$3; Ms. No. 743, Midwestern Psychological Association, Proceedings of the Forty-Sixth Annual Meeting, 29 pages, \$2; Ms. No. 744, Southeastern Psychological Association, Proceedings of the Twentieth Annual Meeting, 83 pages, \$3; Ms. No. 745, Southwestern Psychological Association, Proceedings of the Twenty-First Annual Meeting, 36 pages, \$2; Ms. No. 746, Rocky Mountain Psychological Association, Proceedings of the Forty-Fourth Annual Meeting, 33 pages, \$2.

Payment must accompany orders amounting to \$15 or less. Send orders to JSAS, American Psychological Association, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Below are short reports of the regional meetings. The report of the forty-fifth annual meeting of the Eastern Psychological Association appeared in the September issue (pages 711-713). The New England Psychological Association held its 1974 meeting in November—too late to be included in this issue.

Western Psychological Association

Report of the Fifty-Fourth Annual Meeting

JOSEPHINE FIEBIGER

*Secretary-Treasurer
California State University, Long Beach*

The Fifty-Fourth Annual Meeting of the Western Psychological Association was held April 25-28 at the Sheraton-Palace Hotel, San Francisco. There were 3,673 registrants at the Meeting. The number of association members is 2,755, a total which represents a 23% increase over last year's membership.

The host institutions for the Convention were University of California, Berkeley, and California State University, Hayward. Georgia Babladelis and Milton Blood were the Convention Managers. Other Convention personnel were: Nancy Anderson, Advertising; Sandra Hart, Audio-Visual; David Tieman, Exhibits; Christina Maslach, Film Program; Alan Monat, Housing; Judi Komaki, Placement; Robert Olton and Sheldon Zedeck, Program; Mike Patch, Public Information; Patricia Renwick, Registration; Nicholas Imperato, Social; and Robert Vallon, Volunteers. This year the Program Committee processed about 1,000 program proposals of which approximately 400 papers, 55 symposia, and 20 workshops were accepted. In addition, there were 9 conversation hours, 23 films, and 4 invited addresses. Over 1,100 individuals were listed as formal participants in the program.

At the Board of Directors' meeting, the Status of Women Committee, chaired by Nora Weckler, presented an extensive report on their activities. The

Board of Directors voted to continue its support of the Committee's activities.

The 1974 Business Meeting lacked a quorum and no resolutions were passed this year.

Officers for 1974-1975 are Eleanor E. Maccoby, President; Richard C. Atkinson, President-elect; Paul H. Mussen, Past President; Southern Representative, Neil R. Bartlett; Northern Representative, Irwin G. Sarason; and Secretary-Treasurer, Josephine Fiebiger.

The 1975 Meeting of the Association will be held April 24-26 in Sacramento, California, with California State University, Sacramento, as host institution. George Parrott will serve as Convention Manager.

The 1976 Meeting will be held in Los Angeles, with California State University, Northridge, as host. Nora Weckler and Patricia Keith-Spiegel will serve as Convention Managers.

Midwestern Psychological Association

Report of the Forty-Sixth Annual Meeting

RUDOLPH W. SCHULZ

*Secretary-Treasurer
University of Iowa*

The Midwestern Psychological Association held its Forty-Sixth Annual Meeting in the Conrad Hilton Hotel, Chicago, Illinois, May 2-4, 1974. The program included 408 contributed papers, 7 symposia, 11 invited papers, 2 film programs, and 1 open meeting. Psi Chi presented a session of 8 papers and 2 open meetings. Four invited addresses were given: William K. Estes, Rockefeller University, "A New Look at Probability Learning"; Charles A. Kiesler, University of Kansas, "A Motivational Theory of Stimulus Incongruity with Applications for Such Phenomena as Dissonance and Self-Attribution"; John H. Flavell, University of Minnesota, "Some Perspectives on Human Memory Development"; and Elliot S. Valenstein, University of Michigan, "Evolution of Physical Interventions in the Human Brain." The Presidential Address, "Recent Explorations with a T-Maze: Women's Lib, Long Delays, and All That," was delivered by M. Ray Denny, Michigan State University.

The newly elected officers of MPA are William N.

Dember, University of Cincinnati, President-elect (1974-1975), and Leonard D. Eron, University of Illinois at Chicago Circle, Council Member (1974-1977).

Members of the Program Committee for 1974 were James G. McHose, Southern Illinois University, Moderator; Donald V. DeRosa, Bowling Green State University; Steven J. Sherman, Indiana University; June P. Chance, University of Missouri; Arnold A. Gerall, Tulane University; Martin F. Kaplan, Northern Illinois University; Donald J. Levis, State University of New York at Binghamton; Margaret J. Peterson, Indiana University; and Rudolph W. Schulz, University of Iowa, ex-officio. George S. Speer, Illinois Institute of Technology, served as Convention and Local Arrangements Manager. Local Arrangements Coordinators were Ralph K. Meister, Chicago Jewish Vocational Service, Registration; David W. Bortree, Thornton High School, Placement; Fredric L. Ware, American Personnel Consultants, Mail and Information; Tom Edwards, University of Illinois at Chicago Circle, Public Relations; Eugene Zechmeister, Loyola University of Chicago, Volunteers; and Steven Langer, Abbott, Langer & Associates, Audio-Visual.

The 1975 Annual Meeting will be held at the Conrad Hilton Hotel in Chicago, May 1-3. Donald V. DeRosa, Department of Psychology, Bowling Green State University, Bowling Green, Ohio 43402, will serve as Program Committee Moderator for this year's meeting. Inquiries concerning membership should be directed to Rudolph W. Schulz, Secretary-Treasurer, Department of Psychology, University of Iowa, Iowa City, Iowa 52242.

Rocky Mountain Psychological Association

Report of the Forty-Fourth Annual Meeting

URSULA DELWORTH

*Secretary
Western Interstate Commission
for Higher Education*

The Forty-Fourth Annual Meeting of the Rocky Mountain Psychological Association was held May 8-11, 1974, at the Cosmopolitan Hotel, Denver, Colorado. Registration totaled 675. Membership in the Association totaled 480 as of May 1, 1974.

Irwin W. Cohen served as Convention Manager. Chairpersons of convention committees were: Donald L. Tasto and Thomas L. Bennett, Program; John C. Hocking, Placement; Alice R. Fehrenbach, Publicity; Robert Trustman, Volunteers.

The program included original papers, symposia, workshops, tutorials, movies, and invited addresses. Program cochairperson Donald Tasto reported the papers submitted and accepted to be of higher quality than in previous years.

Richard Weigel, as President of the Association, conducted the annual business meeting. Major announcements and items of business transacted during the meeting were as follows:

1. The next annual meeting is scheduled for May 7-10, 1975, in Salt Lake City, Utah. Meetings will be held in the city Convention Center.

2. Harl Young was named President-elect of the Association by a mail ballot of the members.

3. W. C. Leiding was reelected as Treasurer of the Association for a three-year term.

4. The membership voted to support the following action of the Executive Committee regarding the APA decision to no longer publish proceedings of the regional association meetings: That RMPA communicate objections to this decision to APA, that RMPA write to the presidents of the other six regional associations stating our objections and asking their opinions and what actions they might have taken, and that RMPA write to the chairperson of the APA Publications and Communications Committee questioning whether this is a change in editorial or publication policy.

5. The membership voted to buy institutional membership in both AAP and CAPPS.

6. The membership voted to go on record against cosponsoring a regional meeting of APA.

7. The membership authorized the Executive Committee to pursue incorporation concerns and nonexempt status for the Association, and to take such actions as it can in this regard.

8. Reports were made by all officers and the following committees: Convention—Manager, Program, and Placement; Membership; Committee on Groups Underrepresented in Psychology.

9. No action was taken on adding the province of Alberta to RMPA because the wishes of psychologists in Alberta had not been explored fully.

10. Gregory Kimble was installed as President of the Association.

Full-length proceedings of the regional associations are available through the *JSAS Catalog of Selected Documents in Psychology*. To order the complete proceedings, see details on page 903.

Southwestern Psychological Association

Report of the Twenty-First Annual Meeting

C. EUGENE WALKER

Secretary-Treasurer

University of Oklahoma Medical School

The Twenty-First Annual Meeting of the Southwestern Psychological Association was held at the Paso Del Norte Hotel in El Paso, Texas, on May 2-4, 1974. A total of 420 persons registered for the Meeting. The current membership is 1,594.

Randolph H. Whitworth, University of Texas at El Paso, served as Program Chair; Philip Himelstein, University of Texas at El Paso, was in charge of Local Arrangements; and Paul Whitmore, Human Resources Research Organization, Ft. Bliss, El Paso, was Placement Service Chair.

Vladimir Pishkin, Veterans Administration, University of Oklahoma Health Sciences Center, gave the Presidential Address on Thursday. Joseph D. Matarazzo, University of Oregon Medical School, was the Distinguished Invited Speaker on Thursday. Rogelio Diaz-Guerrero, National Autonomous University of Mexico and Visiting Professor, University of South Florida, was the Distinguished Invited Speaker on Friday.

Winners of the Publisher's Prize were Charles J. Holahan, University of Texas at Austin, and Robert E. Prytula, Middle Tennessee State University. Winners in the Graduate Student Competition cosponsored by Psi Chi were Michael R. Berren, Texas Tech University, first; Robert Breaux, Texas Tech University, runner-up; and William J. Broussard, Texas Research Institute of Mental Sciences, runner-up. Winner in the Undergraduate Student Competition was James M. Williams, Texas Arts and Industries University.

New officers for the Association for 1974-1975 are Logan Wright, President; Vladimir Pishkin, Past-President; Harry J. Parker, President-elect; C. Eugene Walker, Secretary-Treasurer; and the following Council Representatives for the states in the SWPA region: Robert Haygood, Arizona; Philip Trapp, Arkansas; Leon Rappoport, Kansas; Laurence Siegel, Louisiana; Frank A. Logan, New Mexico; Oscar A. Parsons, Oklahoma; and Janet T. Spence, Texas.

The 1975 meeting of the Association will be held in Houston, Texas, April 17-19. William G. Braud will serve as Program Chair; and J. K. Weatherly will

serve as Local Arrangements Chair. Inquiries regarding the annual meetings should be addressed to the Association's central office at P.O. Box 7156, University Station, Austin, Texas 78712.

Southeastern Psychological Association

Report of the Twentieth Annual Meeting

EDWARD H. LOVELAND

*Secretary-Treasurer
Georgia Institute of Technology*

The Twentieth Annual Meeting of the Southeastern Psychological Association was held May 2-4, 1974, in the Diplomat Hotel in Hollywood, Florida. There were 1,255 registrants for the Convention, which met jointly with the Florida Psychological Association and the Florida Association of School Psychologists. The total membership of the Association at the time of the Meeting was 1,862. Joseph C. Hammock, University of Georgia, was Program Chair. Wallace Wilkins, University of Miami, chaired the Local Arrangements Committee. Michael Epstein, University of Miami, was Director of Placement. Under the auspices of its Continuing Education Committee, the Association sponsored six preconvention professional workshops, which were well attended.

Special programs which were held in conjunction with the Meeting were the annual all-day meeting of the Southeastern Society for Multivariate Experimental Psychology, with Harry E. Anderson, University of Georgia, presiding; the Southeastern Regional Psi Chi meeting and invited address with William Grossnickle, East Carolina University, presiding, and Sidney Jourard, University of Florida, speaking on "Within Freedom and Dignity: The Task of Humanistic Psychology."

Other groups which met during the Convention included the Southeastern Workers in Memory, the Southeastern Region State Psychology Boards, and the Southeastern Association of Heads of Departments.

William D. Spears delivered the Presidential Address, "On the Operant Behavior of Unicorns," immediately preceding the business meeting of the Association.

During 1973-1974, the Executive Committee of the Association was composed of William D. Spears, Presi-

dent; Joseph C. Hammock, President-elect; Charles D. Spielberger, Past-President; Edward H. Loveland, Secretary-Treasurer; and Members-at-Large Raymond Shrader and Laurence Siegel.

Officers for 1974-1975 are Joseph C. Hammock, President; Marshall Jones, President-elect; and Edward H. Loveland, Secretary-Treasurer. Past-President is William D. Spears, and Members-at-Large of the Executive Committee are Laurence Siegel and Ellen Kimmel.

Southern Society for Philosophy and Psychology

Report of the Sixty-Sixth Annual Meeting

MICHEL LOEB

*Secretary
University of Louisville*

The Sixty-Sixth Annual Meeting of the Southern Society for Philosophy and Psychology was held on April 11-13, 1974, at the International Inn in Tampa, Florida. Hosts were the Departments of Philosophy and Psychology at the University of South Florida. Approximately 200 members, friends, and guests were in attendance.

The Program consisted of 36 papers in philosophy and 47 papers in psychology, in addition to two symposia in psychology and three joint sessions. One of the philosophy sessions was a colloquy in honor of Erwin W. Straus. As usual, a social hour and business session were included in the program.

The first joint session was a symposium regarding women, philosophy, and psychology. Participants included Mary Anne Baker, William T. Blackstone, Clyde E. Noble, and Dwight Van de Vate. At the second, Douglas Browning, University of Texas, introduced Lelon J. Peacock, University of Georgia, who delivered the Presidential Address, "Ionizing Radiation and Behavior." At the third joint session, Duane Rumbaugh, Georgia State University, delivered an invited address, "Automated Language Training of the Chimpanzee, Lana." Discussants for Dr. Rumbaugh's address were Donald E. Nute, University of Georgia (Philosophy), and Herbert D. Kimmel, University of South Florida (Psychology).

Two Richard M. Griffith Memorial Awards were announced. The recipient in Philosophy was Dr. Roger J. Sullivan of the University of South Carolina for his paper, "The Kantian Critique of Aristotle's Philosophy: An Appraisal." The recipient in Psychology was Dr. Mary-Ellen O'C. Chernovetz of the University of Tulsa for her paper, "Repeated Exposure to X-Radiation and Radiation-Induced Taste Aversion." These awards are given annually for the papers of highest merit by members who have not yet received the doctoral degree or who have received it within the last five years.

Cochairs of the Committee on Local Arrangements were James Gould (Philosophy), University of South Florida, and Herbert D. Kimmel (Psychology), University of South Florida. Cochairs of the Program Committee were Frank R. Harrison III (Philosophy), University of Georgia, and Norman R. Remley (Psychology), Texas Christian University. Cochairs of the Richard M. Griffith Memorial Awards were Douglas Browning (Philosophy), University of Texas, and Stanley B. Williams (Psychology), College of William and Mary. Cochairs of the Membership Committee were Clyde E. Noble (Psychology), University of Georgia, and Donald Sherburne (Philosophy), Vanderbilt University.

At the Annual Business Meeting, reports of the officers and of several standing ad hoc committees were received and accepted. It was announced that the 1975 Annual Meeting would be held in the Marriott Inn in New Orleans, Louisiana, under the joint sponsorship of the Departments of Philosophy and Psychology of Tulane University on March 27-29.

The deaths of members Robert C. Wingfield and Alvin Nelson were noted with sorrow.

Thirty-three philosophers and thirty-four psychologists were elected to full or associate membership in the Society. Frank A. Geldard and Erwin W. Straus were elected Honorary Members for Life. Full and

associate members elected were:

Full Members, Philosophy: Robert Almeder, Lynne R. Baker, Margaret A. Balinsky, Ronald L. Barnette, Peter A. Bowman, George Brenkert, L. Hughes Cox, Richard E. Creel, Daniel T. Devereux, Ronald H. Epp, Ash Gobar, Alfred H. Guy, Jr., H. Phillips Hamlin, James R. Harris, Donald S. Klinefelter, Betsy P. Latta, Donald W. Livingston, Ruth Manor, Stephen A. McKnight, Delos B. McKown, Eben S. Moulton, Kai Nielsen, M. A. C. Richter, E. W. Van Steenburgh, James L. Stiver, Roger J. Sullivan, Paul E. Tibbetts, Jeffrey Tlumak, Frank C. Williams, and John J. Young.

Full Members, Psychology: James A. Beshai, Sue Bogner, Robert L. Breckenridge, Allen Blomquist, Darryl Bruce, Barbara L. Canter, Kyle R. Carter, Mary Ellen O'C. Chernovetz, Catherine S. Davison, William B. Dragoin, Katherine Ernst, Rose Frank, Jack N. Haney, Robert E. Hicks, Charles S. Noble, Shirley W. Osgood, Milton S. Palanker, Andrew J. Pavlos, Florrie M. Pennington, John W. Porter, Jack B. Rollins, Dewey Rundus, Kendon Smith, John R. Stabler, David J. Stang, Paschal N. Strong, Jr., and George J. Vesprani.

Associate Members, Philosophy: John N. Hooker, Jr., Stephen Skousgaard, and Michael E. Zimmerman.

Associate Members, Psychology: Brenda J. Clower, Franklin J. Euse, Sam J. Hagan, Richard P. Honeck, Keith W. Jacobs, Gary L. Snethen, and H. Roger Wilkerson.

The following officers were elected to serve during 1974-1975: William T. Blackstone, University of Georgia, President; Clyde E. Noble, University of Georgia, President-elect; Donald Sherburne, Vanderbilt University, Treasurer; Nancy Simco, Memphis State University, to a three-year term on Council for Philosophy; Joel S. Warm, University of Cincinnati, to a three-year term on Council for Psychology; and Frank R. Harrison III, University of Georgia, to a one-year term on Council for Philosophy. Continuing members of the Council include Mary Ellen Curtin, Veterans Administration Hospital, Lexington, Kentucky; Thomas K. Hearn, College of William and Mary; and Norman R. Remley, Texas Christian University. Michel Loeb, University of Louisville, continues to serve as Secretary.

APA Visiting Scientist Program: 1973-1974

EDUCATIONAL AFFAIRS OFFICE

The American Psychological Association's Visiting Scientist Program has now completed its fourteenth year. Support for the program was provided by a grant from the American Psychological Foundation, contributions from the institutions visited, and budgeted funds from the American Psychological Association.

As in the past, the Visiting Scientist Program provided colleges and small universities with visits from eminent psychologists who offered their services as either scientific lecturers or educational consultants. Over 1,000 such visits have been made to educational institutions across the United States, 70 of which were made during 1973-1974.

Throughout its existence the program has maintained the following objectives: (a) to stimulate interest in the scientific aspects of psychology at the collegiate

level; (b) to present some of the new developments in psychological research and application; (c) to provide psychology departments with expert consultation regarding curricula, laboratories, staffing, programs, and procedures; (d) to acquaint students with the opportunities for advanced study and scientific and professional careers in psychology, including the teaching of psychology. For the last several years a special effort has been made to include psychologists and institutions which would serve as representatives of minority groups.

The reports of the visits were very favorable and the Educational Affairs Office would like to express its appreciation to all of those who contributed to the success of this year's program.

TABLE 1

Institutions Visited in the 1973-1974 Visiting Scientist Program

Institution	Visitor
Adrian College Adrian, Michigan	Donald R. Brown University of Michigan
Albany State College Albany, Georgia	Lawrence W. Littig Howard University

APA Visiting Psychologist Program: 1973-1974

EDUCATIONAL AFFAIRS OFFICE

The NIMH-sponsored Visiting Psychologist Program has completed its seventh year of operation. This program is designed to facilitate the dissemination of current knowledge generated in recent research findings and to provide for the demonstration of innovations in psychological research to mental health professionals. The program attempts to reach practitioners in service settings by offering consultation, lectures, and demonstrations by psychologists who are themselves significantly involved in research, training, and delivery of services. During the 1973-1974 program year, 49 agencies were visited, of which 38 were newly selected agencies and 11 were return visits to agencies visited the previous year. Forty-eight psychologists participated as visitors in the program. Agencies that received initial visits are listed, with their Visiting Psy-

chologists, in Table 1. Agencies and Visiting Psychologists involved in return visits are listed in Table 2.

The program is administered by the professional staff of the Educational Affairs Office and is under the general supervision of the Education and Training Board. An Advisory Committee, the current members of which are Stanley Brodsky, Mildred Buck, Ruth Lesser, William Pierce, and Arthur Wiens (Chair), monitors the program. The Advisory Committee would like to thank all those who contributed to the success of this year's activities.

The selection of agencies for the program has been guided by the same broad criteria since the inception of the program. The target group continues to be those agencies wherein psychologists are employed in a professional role but where there is little in the way

TABLE 1

Agencies Receiving Initial Visits in the 1973-1974 Visiting Psychologist Program

Agency	Visitor
Alaska Board of Psychologist Examiners Fairbanks, Alaska	Sumner Morris University of California

Rutherford County Guidance Center Murfreesboro, Tennessee	J. L. Khanna University of Tennessee
Tidewater Mental Health Clinic Williamsburg, Virginia	John McMillan George Washington University

of resources to provide outside stimulation and exposure to new developments in the field. The program tries to provide consultation and continuing education service to agencies that might go unnoticed in most efforts directed at broad dissemination of knowledge.

The program has endeavored to recruit visitors with special qualifications to meet the special needs of the agencies that have applied. Wherever possible, visitors are paired with agencies on a regional basis in order to keep travel expenses at a minimum. An additional benefit of this regionalized pairing has been the development of more lasting relationships between visitors and agencies.

Last year it was reported that the Visiting Psychologist Program was in its final year of support by NIMH (Educational Affairs Office, 1973). We are pleased to report now that the grant funds have been restored by NIMH for the 1974-1975 year and that a full program of visits will take place. During the coming year it is expected that the Visiting Psychologist Program will continue to follow a trend toward greater flexibility and broadened scope. This trend includes attempts to reach larger numbers of agencies which serve primarily disadvantaged or minority clientele to make

increased use of minority psychologists as visitors to send more than one visitor when the problems presented by the agencies are unusually complex and to reach more local professional groups of psychologists.

The use of graduate students as visitors who accompany the regular Visiting Psychologists has become an important and highly successful feature of the program. Last year 16 graduate students participated. They provided significant consultation service to the agencies and also had a unique training experience. Furthermore the opportunity to take students on visits has made the Visiting Psychologist Program more attractive to the visitors.

Agencies wishing to apply or anyone wishing to nominate agencies for participation in the Visiting Psychologist Program should write to Ronald B. Kurz at the Educational Affairs Office, APA Central Office, 1200 Seventeenth Street, N.W., Washington, D.C. 20036.

Gold Medal Award

The Trustees of the American Psychological Foundation invite the members of the American Psychological Association to nominate candidates for the 1975 Gold Medal Award. The Award is given to an American psychologist in recognition of a distinguished and long-continued record of scientific and scholarly accomplishments. The Award is limited to psychologists 65 years of age or older and is also limited to those residing in North America. Nominations should be accompanied by a statement highlighting the accomplishments of the nominee. Nominations should be addressed to: Secretary, American Psychological Foundation, 1200 Seventeenth Street, N.W., Washington, D.C. 20036, to be received no later than March 15, 1975. Decisions will be made by the Trustees of the Foundation.

Comment

How High Are the Odds Against Women?

Bernstein and Russo (February 1974) point with pride to the achievements of earlier women psychologists and conclude that these pioneers worked against adverse circumstances and incredible odds. Think, they say, what we could do if we had an equal chance. Fortunately these earlier women did not seem to be aware of adverse circumstances and incredible odds and, in the usual way, they saw things not as things are but as they were. Historically, all significant contributors, male or female, have faced the odds and won.

In a preliminary quiz, Bernstein and Russo tested the reader's knowledge of some productive women. This reader, a "foremother" in time if not in eminence, made a high score. It can be taken for granted that a worker in a field will know by work and by sex who has accomplished what. To the authors' list, I would add Bluma Zeigarnik (of the Zeigarnik Effect) and Tamara Dembo who, with Maria Ovsiankina, worked in the 1920s with Kurt Lewin in Germany; also Myrtle McGraw, Leta Stetter Hollingworth, and Harriet Babcock in New York. Among women who worked with Terman, add Melita Oden. Then, if Anna Freud, Melanie Klein, and Karen Horney, why not Susan Isaacs, Helene Deutsch, and Marie Bonaparte?

Like men, women of talent and determination make their way, regardless of climate. If there is discrimination, they find a way around it. When publishers would accept only male authors, Jane Austen, the Brontë sisters, George Eliot, and George Sand, among others, wrote under male pseudonyms; time has taken care of the rest.

Going back to the Greek dramatists, one finds a gallery of women

bewailing their powerlessness, but as dauntingly formidable as any member of their sex ever seen on or off stage. And, perceptively, the Greeks embodied wisdom in a feminine figure. Bewailing their grievances while wisely exercising real power has proved to be an effective feminine pattern.

Shakespeare's women were certainly no repressed house drudges. Portia is the epitome of the fully developed personality, a good friend for a man to have, if not easy to live with. No one exposed to England's Elizabeth I could conclude that women were inferior in any way, or that a women judge was unusual.

Of more recent foremothers, the list of outstanding women reaches into space. Even in the less feminine fields there are Lise Meitner and Marie Curie in physics; Helen Wills, May Bundy, and Suzanne Lenglen in tennis; Gertrude Ederle and Annette Kellerman in swimming; Aline Saarinen and Ada Louise Huxtable in architectural criticism; Simone Weil, Hannah Arendt, and Susanne Langer in philosophy. For years, Sylvia Porter has written a financial column; women specialists on Wall Street write and appear on television; Claudia Cassidy, a longtime music critic in Chicago, made and unmade reputations; in the political arena, Rosa Luxemburg, Emma Goldman, La Pasionaria, Indira Gandhi, and Golda Meir; in foreign correspondence, Dorothy Thompson, Dorothy Kilgallen, and Margaret Bourke-White; in creative choreography, at one time a male field, Martha Graham, Doris Humphrey, Ruth St. Denis, and Anna Solow.

In painting, we find Vigee Le Brun, Rosa Bonheur, Marie Laurencin, Berthe Morisot, and Mary Cassatt, whose work was hung in Paris when Cezanne was rejected. Kathe

Kollwitz, a wife and mother, pursued her art in early twentieth-century Germany with the full cooperation of her husband and of society. Louise Nevelson is considered by some to be America's foremost sculptor.

Among Nobel Prize winners are Sigrid Undset, Selma Lagerlof, Nellie Sachs, Grazia Deledda, Gabriela Mistral, and Pearl Buck in literature; Marie Curie and Maria Goeppert-Mayer in physics; Irene Joliot-Curie and Dorothy Crowfoot in chemistry; Gerty Cori in medicine; Baroness von Suttner and Jane Addams for peace. Among Pulitzer Prize winners for fiction, poetry, drama, historical writing, and journalism, the feminine names are too numerous to list.

Women have always played a large part in music. If one eminent pianist finds that her career excludes motherhood, another, equally eminent, is a mother and grandmother, and tours and records in her late seventies. How great the talent and the will to utilize it depends on the individual. Women have been musically trained in large numbers, and no prejudice exists. Women composers (and there are several hundred of them), contrary to public opinion, were neither stifled nor denied an audience. If there are no Bachs and Beethovens among them, only one Bach and one Beethoven appear among thousands of male composers (Rubin-Rabson, 1973).

In early nineteenth-century Germany, hardly known for its liberal attitude toward women, Clara Schumann, wife of Robert, was a touring virtuoso, a sought-after teacher, a gifted composer; she also bore eight children and supported the household on her earnings. In the same period, Louise Bertin, a gifted French writer and composer, wrote an opera to a libretto by Victor Hugo; the opera

was performed. If it has disappeared, so have most other operas.

French composer Germaine Tailleferre heard her own works performed in public by famous artists and orchestras. Ethel Smythe, a suffragette and composer, was made Dame of the British Empire for her compositions. Nadia Boulanger, herself a winner of the Prix de Rome, has been a teacher of nearly every composer since 1920, but modestly admits to little merit in her own compositions. Marion Bauer, a professor of music at New York University, was recognized by critics as competent, and her work was widely performed. She professed to be pleased with her success and her treatment in the critical musical world but "had no specific goal nor definite plan to do anything important [Rubin-Rabson, 1973]." Talent alone is not enough; the imperious urge to accomplishment must be present as well.

Professional women, psychologists as well as others, show characteristics somewhat aberrant from the norm (Bachtold, 1970; Ross, 1973). They are independent, self-sufficient, competitive. A large number are single, allowing them to work more single-mindedly than their family-responsible male colleagues. Among the married, the divorce rate is high, children absent or few. There is, then, no lack of working time. However, with or without home distractions, the professional woman has only so much personal substance to expend. The more involved she is with activities outside of her prepared field, the more she must leave to others those productions that result in recognition in the field.

As women move rapidly into all areas, the competition increases, but unfortunately they still seem to move into the same old areas. Matina Horner (1974), associate professor of psychology at Harvard, mother of three and at 32 already president of Radcliffe College, said recently, "Radcliffe's entering freshmen often express strong desires to major in esoteric [!] areas such as physics and chemistry, but along the way . . .

change their majors and settle for easier subjects." The behavioral sciences?

This situation is not unique to American women. In Switzerland ("Congestion in Psychology Courses," 1972), the number of students in psychology has doubled in four years, compared to a 5% increase in the top technical schools. A large number of women are seeking marriage preparation, not professional skills, and are using the university as a "waiting room peopled by many men." Another group is looking for "snap courses," or a solution to personal problems, or has some philanthropic urge to aid others. The dropout rate, however, is a university lifesaver. Of all 1961 matriculates, only 33% finished the course, compared to 86% of law students, and 82% of medical students. In 1970, among those choosing psychology as a major subject, 50% had dropped out by the end of the fourth semester.

In psychology, or in any other pursuit, no one, male or female, is "given an equal chance." With talent and will, one "makes an equal chance." The foremothers, hard-working and undeterred, would say: "My daughters, discrimination, like fear, knocks on the door; one rises to open; there is no one there. Forget your grievances, dry your tears, and get to work."

On the Role of Mental Health Workers in the Criminal Justice System

Silber (April 1974) attempted to describe and justify guidelines for the development of a role for mental health workers within the criminal justice system and existing correctional settings. His defense was disturbing in that he made a number of contradictory statements concerning the issues of mandatory treatment, the receptivity of the correctional system and prisoners to mental health workers, and the manner in which one should fulfill one's responsibilities as the therapist to the prisoner-client. Silber's difficulties in the handling of these issues are worth noting because they point out some of the basic conflicts which must be overcome if mental health workers are ever to play a more meaningful role in the treatment of offenders than the role prescribed by Silber.

1. Silber seems ambivalent and frequently inconsistent in his statements about mandatory treatment for prisoners. He claims to eschew mandatory treatment in principle (p. 243) and urges that the prisoner must make the decision as to whether he will receive treatment. On the other hand, Silber believes that:

Diagnosis and classification should occur as soon as the offender is incarcerated. . . . the results should be discussed at a case conference. Major decisions concerning diagnosis, therapy, and placement with the system would be made there [p. 242].

These results are to be used to "motivate the prisoner to get involved in his own rehabilitation [p. 242]." The major issue is whether such procedures in practice, occurring as they would in a controlling and somewhat threatening environment, might constitute direct or indirect coercion of the prisoner (which Silber advises against on p. 243) to participate in treatment. To refuse treatment in such a system would be to risk being labeled uncooperative or negativistic (Brodsky, 1973), to which extent coercion would be inherent in Silber's procedure. Furthermore, the inten-

tion to "motivate" prisoners to become involved in treatment is in itself a treatment goal, suggesting that in fact some sort of psychological intervention designed to change attitude or behavior would be mandatory and part of the admission process for all prisoners. Silber avoids discussing this issue in the article.

2. Silber recognizes that many prisoners might not accept offers of treatment readily, but he feels that many could be brought to do so if they were "treated as . . . dignified and reasonable human being[s]" [p. 242]. While this view might have merit, it is doubtful that many prisoners would be responded to in this manner if they were viewed by the majority of mental health workers as they are described by Silber, that is, as "some variation of the character disorder/psychopathic personality label." Such prisoners are hostile, suspicious, and immature [p. 242]. The latter characteristics do not necessarily follow from the diagnostic categories mentioned, and the diagnostic statement itself represents an overgeneralization concerning prison populations. In six of the nine studies of psychiatric evaluations of offenders reviewed by Brodsky (1973), from 41% to 85% of the offenders were evaluated as "normal." Brodsky concluded that our present knowledge of offenders does not allow us to presume homogeneity (see also Dean, 1973). It is precisely the stereotyping of prisoners which Silber demonstrated that would make it difficult for many mental health workers to approach a prisoner as "dignified and reasonable."

3. Silber feels that treatment efforts with offenders should occur within existing correctional programs because they "have the practical advantages of being already in existence" and have "avowedly rehabilitative goals [p. 241]." On the other hand, Silber recognizes that the staff members of prisons "usually view the professional staff with ambivalence or outright hostility [p. 242]." Such hostility is in part a result of the infusion of those with *rehabilitative* goals into a system which has a

long tradition of *retributive* goals. That such institutions are "already in existence," then, is at least as much a liability as an asset with regard to the establishment of effective treatment programs within these institutions. In addition, whether or not such institutions "avow" rehabilitative goals is irrelevant; given the long-standing fear, suspicion, and commitment to retribution which Silber admits are the hard realities frequently confronting the mental health worker in the correctional system. Finally, one can argue that the routine of prison life necessary to maintain security (Sutherland & Cressey, 1970, chap. 23) is antithetical to the implementation of a treatment "'package' tailored to the individual [p. 242]" which Silber recommends.

4. Silber argues that in the correctional system, as in other treatment settings, "the first concern of the therapist is the client [p. 242]." In attempting to practice this maxim in my own work with institutionalized delinquent boys, I have sometimes felt that I have failed before I have begun because I have had no power to avert a boy from commitment to the institution itself. The institutional experience does not have marked negative effects on all prisoners, but it does on some: In the case of delinquent adolescents, the issue of frequently needless or ill-advised institutionalization has been recognized (e.g., Rose, 1972; Sutherland & Cressey, 1970). Decisions occur in the courts concerning whether an offender will be institutionalized, yet Silber counsels mental health workers to "stay out of the adjudication process and in the correctional system [p. 241]." Thus he disallows any mental health workers as advisers to the court concerning probationary or dispositional decisions which might be in the best interests of the offender. Since the offender potentially is destined to be a "client," who is the "first concern of the mental health worker," in the correctional system, it seems inconsistent that there should be no input by mental health workers at the point

when the offender's "client" status is determined, especially in the case of juvenile offenders.

It would seem, then, that Silber's suggestions for mental health workers in correctional settings are not those which could be executed without exhibiting in one's thoughts and actions the same sort of inconsistencies which appear in Silber's argument. This does not mean that one could not develop a more meaningful role for professionals in correctional settings.

In searching for a more viable role for mental health workers, however, we should probably: (a) focus our attention *first* on modification of correctional staff attitudes and system variables, and *then* on providing treatment to individual offenders themselves; (b) decide whether to accept or reject, for all, some, or no offenders, the idea of mandatory treatment, and then defend and practice our decision without pretense; (c) begin to refine sufficiently our views of offenders and treatment methods appropriate for them so that we do not fall prey to the stereotyping and generalization that have plagued this area; and (d) not feel bound to confine ourselves to roles within correctional institutions—that is, explore ways in which the mental health professional may assist the offender at the postinstitutional (release) phase (see Erickson, Crow, Zurcher, & Connett, 1973) and may act as consultant to the court during the preinstitutional (probation and disposition) process.

Reflections on "Reflections on Introspection"

Radford's (April 1974) reflections on introspection make a number of substantive statements about introspection as event and process. However, his reflections reflect prevalent misconceptions and distortions of the behaviorist view of the status of introspection in psychological inquiry. First, he pursues an argument which is a misstatement of the behaviorist position; and he then avoids reckoning with empirical as opposed to doctrinaire grounds underlying the behaviorist emphasis on behavior. He thus annihilates a straw man. The following is an attempt to clarify the behaviorist position.

First, those who pursue knowledge within a scientific framework of inquiry know that all data are admissible insofar as they are replicable and communicable. The relevance of any reliable data to theory building, prediction, and control is an empirical question and as such is not to be decided by definitional fiat or on a priori grounds. Further, the inclusion of particular events as data within an area of general inquiry is necessarily a function of available and publicly verifiable conditions for their observation, as well as of the theoretical and empirical utility of such data. Again, definitional fiat provides no scientific ground for the exclusion of data. The proper scope of a subject matter is, like that of all sciences, loosely defined, continuously evolving, and therefore open to both empirical possibility and theoretical advantage. So, for example, chemistry as science, once

defined as "the study of matter," properly and necessarily incorporated what was seen as nonmaterial (or nonmatter) concepts, such as valence, later developed into electrical charge, into its domain, once the technology was developed whereby such theoretical constructs and hypothesized laws involving them could be verified empirically. As a result, electromagnetic theory and action are currently central to the understanding of the actions and reactions of matter. If we may speculate by analogy, it is reasonable to similarly avoid a priori limitations on the exploration of potentially "interesting" data such as introspection. There is no behaviorist argument with Radford here.

Radford errs when he cites the doctrine of objective experiment and confounds this doctrine, which is obviously a methodological given for behaviorists, with an alleged doctrine of behaviorist psychology, namely, that the proper and presumably only acceptable subject matter of psychology is behavior and that data regarding conscious experience obtained by the process of introspection and made public through verbal report are off limits. Now it just is not the case that behaviorism rejects introspection as process with or without the data of verbal report. The behavioristic view is to treat verbal report as data (verbal behavior), and of course such data are obtained through the process of introspection. However, it is also true that data obtained through the process of introspection (one may seriously question whether introspection is a single process or reflects different processes depending on the conditions of inquiry) are unreliable and poor predictors, and that such data, in the traditional and currently available methods of ordering and conceptualizing them, have not been demonstrated to have predictive and therefore empirical power.

Now data that do not appear to be significant under some conditions may be so under others. It remains for whomsoever of the behavioristic,

humanistic, psychoanalytic, etc., schools interested in public inquiry to conceptualize introspectively obtained findings in a way that advances theory and applications. This is what science is and no more, and arguments over whether introspection exists and whether the results of introspection constitute the subject matter of psychology are spurious. The issue is whether the procedure and the data can be used in lawful ways. It is one thing to stand with both feet in the camp of science and to look and work for lawfulness using introspection. It is something else to stand with one foot in science and the other in a body of statements (verbal reports?) which, after 100 years of trying, have not been conceptualized in a form that provides scientific meaning in more than the immediate self-observational sense and to loudly proclaim the import of these data. Let those who are dedicated to the import of particular data study them and articulate their meaningfulness.

Behaviorist psychology is a field of intervening variables to which introspectively obtained data might be fitted (Edwards, 1954; Goldiamond, 1958; Mowrer, 1960; Solomon & Wynne, 1953; Swets & Birdsall, 1955; Tanner & Swets, 1954). I suggest that those interested in developing the relation between introspection and behaviorally derived findings and theory continue to work at it as an alternative to making pseudoarguments against a pseudoposition.

A final analogy with another domain of inquiry with similar problems may be instructive. The status of pain in medical-physiological inquiry is in certain ways comparable to the status of conscious experience in behavioral-psychological inquiry. The major access to the observation of pain is through the subject's introspectively obtained verbal report. The verbal report which makes public the pain event has been shown to be more reliable, more precise, and more sensitive than any other measure (such as GSR) or combination

of measures (such as GSR or respiratory rate), and has therefore useful and respected status as an indicator of independently observable events, for example, pinpricks. This reliability, accuracy, and precision force the scientific observer to accord the verbal report of pain special status as an indicator of physiological malfunction which stands even where other observational procedures fail (as in headache or gastrointestinal disorders), although the verbal report of pain is neither necessary nor sufficient to define a physical trauma. Thus, verbal report of pain is of great utility although there may be physical trauma without pain, or reported pain without apparent physical defect but with defect presumed (as in headache), or reported pain with insignificant likelihood of associated physical defect (as in psychogenic pain). Reported pain is taken as a real event, primarily because all observers experience it. But more important scientifically, correlates such as tissue trauma are discovered; so are other indicators such as heart rate, behavioral reactions, and so on. There is no doubt of the existence of pain nor of its significant relationship to other observable events. Reported pain thus has a diagnostic value, has a predictive value, can be reduced to the physiological terms of neural receptors and networks, and thus has powerful theoretical import.

Similar characteristics hold for some introspective data in psychology, as in the experimental study of dream reporting and its correlates (Dement & Wolpert, 1958), and such work is likely to be expanded into other areas of study. Only as wishing won't make it so, neither will misdiagnosis of the commitment of behaviorism to empiricism as a thesis denying the existence or potential utility of introspectively gained data make it so.

Open Minds and Ideology

In response to my comment (Dworkin, June 1974) on the shift in his views between 1967 and 1969, Jensen (June 1974b) says he has changed his mind, and that is the mark of a scientist as opposed to an ideologue. He also deplores any contamination of psychology with political ideology. He has changed his mind because he has tested 15,000 more children, read the Coleman report, and learned some quantitative genetics.

On the politically and educationally most crucial issue—the presence of racial genetic differences in IQ—Jensen has continued to change his mind. It is instructive to follow his development and bring it up to date.

In 1967, Jensen's position was:

since we know that the Negro population for the most part has suffered socioeconomic and cultural disadvantages for generations past, it seems a reasonable hypothesis that their low average IQ is due to environmental rather than genetic factors [p. 10].

In 1969, Jensen stated:

So all we are left with are various lines of evidence, no one of which is definitive alone, but which, viewed all together, make it a not unreasonable hypothesis that genetic factors are strongly implicated in the average Negro-white intelligence difference [p. 82].

Note by the way the crucial ambiguity of the phrase "strongly implicated." On the one hand it could mean that it is strongly (highly probable) implied that genetic factors play some role; on the other, it could mean that it is implied that genetic factors play a strong (major) role. For someone writing on an issue of such moment to phrase his conclusions in such an ambiguous way is, at the least, negligent.

In 1973, Jensen claimed:

All the major facts would seem to be comprehended quite well by the hypothesis that something between one-half and three-fourths of the average IQ difference between American Negroes and whites is attributable to genetic factors, and the remainder to environmental factors and their interaction with the genetic differences [p. 363].

I fail to understand how testing 15,000 children (or 15,000,000), reading any number of reports on compensatory education, and least of all learning some behavior genetics could lead anyone to make the last claim. Thoday (1969), Gibson, Mascie-Taylor, and Thompson (1972), Lewontin (1970), Cavalli-Sforza and Bodmer (1971), Layzer (1974), and others have pointed out the insuperable obstacles, both theoretical and empirical, to making any quantitative claims of that nature about subpopulation differences, either between social classes or between races.

As to the role of ideology, it seems to me that Jensen's (1973) following attitude toward the promulgation of hypotheses must be influenced by a specific weighting of the values of scientific knowledge versus the possible social consequences of one's work:

There are always differences among investigators working on the frontiers of a field. They differ in their weight-

ing of items of evidence, in the range of facts in which an underlying consistency is perceived, in the degree of caution with which they will try to avoid possible criticisms of their opinions, and in the thinness of the ice upon which they are willing to skate in hopes of glimpsing seemingly remote phenomena and relationships among lines of evidence which might otherwise go unnoticed as grist for new hypotheses and further investigations. On all these points we [Jensen and his critics] differ in varying degrees, and my own inclination is perhaps to be somewhat less conservative than would be some other students in dealing with the central topics of this book. My own reading of the history of science, however, leads me to believe that conservatism in generating hypotheses and in seeking means for testing them has not made for progress as often as a more adventurous approach [pp. 3-4].

Being adventurous may be admirable when the risks of such adventures are born by the adventurer or by others who consent to such risks. In this matter Jensen faces only the risk of being wrong in his speculations; others face the risk of increased political, economic, and educational oppression.¹

With respect to pessimism about the prospects for improving educability by environmental means, again it seems to me that one's degree of optimism or pessimism is necessarily, in part, a function of one's ideology. By ideology I mean here the most general, fundamental, and usually unexamined beliefs about human nature and its limits, the kind of knowledge we can have on such matters, the relationship of human nature to normative issues, the limits set by biology to political possibility, and the use of science to rationalize (or change) existing social and economic relationships.

Jensen (1969) said: "Compensatory education has been tried and it apparently has failed [p. 2]." Compare, for example, Bereiter's (1971) conclusions from the same set of facts:

To treat the eventual vanishing of preschool effects as failure is to imply either that preschool compensatory education is futile or that the effective method has yet to be discovered. Either of these conclusions *could* be true, but those who think they follow from current evidence are applying criteria of success to preschool education that are not applied in any other realm of human effort. They are asking the doctor for a pill they can take when they are ten that will prevent them from getting fat when they are fifty.

Reason would have it that if we have designed a preschool program that produces benefits lasting for three years, then instead of agonizing that they didn't last for five or ten, we should be concerned with what can be done in the years after preschool to produce further benefits [p. 13].

One's hopes also ought to be, of course, a function of what has been tried and of what our best available theories tell us.

In fairness to Professor Jensen, he has recently indicated a change of mind in the opposite direction. In 1972, Jensen wrote of Burt's work on the genetics of mental abilities:

This is the work that will most probably secure Burt's place in the history of science. [Burt's studies consisted of] larger, more representative samples than any other investigator in this field has ever assembled. . . . These studies, since corroborated by more recent investigations, scientifically established that genetic factors are the predominant cause of individual differences in mental ability [p. 117].

In 1974, Jensen concluded after a thorough study of Burt's data on kinship correlations with their "unknown, ambiguous, or inconsistent sample sizes":

the correlations are useless for hypothesis testing. Unless new evidence rectifying the inconsistencies in Burt's data is turned up, which seems doubtful at this stage. I see no justifiable alternative conclusion in regard to many of these correlations [1974a, p. 24].

It is unfortunate that social policy is made on the basis of such shaky data. All of us who deal in the realm of ideas would do well to remember the philosopher Bradley's warning that "ink and paper can cut the throats of men." When we are

concerned with the minds of children, that warning takes on added force.

GERALD DWORKIN
Department of Philosophy
University of Illinois
at Chicago Circle
Visiting Fellow
Battelle Seattle Research
Center

The Republican Party and Santa Claus

I would like to congratulate Dworkin (June 1974) on his cogent analysis

¹ For an extensive discussion of this and related issues, see Block and Dworkin (in press, Part II).

of the shift of views by Jensen. Why didn't anybody think of it before? Back in 1967 there were many American children who believed in Santa Claus, but by 1969 they had completely shifted to disbelief in the whiskered gentleman. Could this shift be because of new information? Of course not—it was the changing political, intellectual, and social currents in American society.

The level of criticism aimed at Jensen has unfortunately sunk to personal attacks on the man and not at the research itself. Such attacks will shed no new light on the subject of genetic differences in intelligence nor give impetus to further research to prove or disprove Jensen's theory.

I would like to think that such thinly veiled cheap shots at the in-

tegrity of a researcher by impugning his motives has no place in psychology.

NOTICE TO APA AUTHORS

The American Psychological Association announces publication of the second edition of the *Publication Manual* in August 1974. This new edition, which supersedes the 1967 Manual, will be adopted by the 14 APA journals in 1975.

The new Manual is more comprehensive than the previous edition. It updates APA publication policies and procedures and incorporates changes in editorial practice since 1967. For instance, APA now sends many authors their copy-edited manuscripts for review before they are set into type, and some editors now use blind review procedures. The second edition also includes up-to-date statements of the coverage of each APA journal including the *Journal of Experimental Psychology* which will be published in four separate sections in 1975.

The new *Publication Manual* initiates several changes in APA style. These changes are announced in the August 1974 *American Psychologist* and will be introduced in the APA journals in January 1975. During the period of transition to the new style, authors should note that (a) all manuscripts published in 1974 will be copy-edited according to the 1967 Manual, (b) manuscripts accepted in 1974 and published in 1975 will be copy-edited to conform to the new Manual. Starting in 1975, accepted manuscripts that depart significantly from the Manual will be returned to authors for correction.

Authors will be encouraged by the changes in the second edition. The new APA style simplifies reference forms; eliminates unnecessary underlines, brackets, and other devices; supports appropriate use of "I" and "we"; and generally clarifies typing requirements. Material is arranged for maximum convenience to authors and typists, and all sections are cross-referenced and indexed.

The new *Publication Manual* is available after August 1 for \$3. Send orders to APA Publication Sales, 1200 Seventeenth Street, N.W., Washington, D. C. 20036. Orders of \$15 or less must include payment unless they are submitted on institutional purchase order forms.

Fellowships and Postdoctoral Programs

Devereux Foundation Institute of Clinical Training: Applications are available for the predoctoral internships and postdoctoral fellowships in clinical psychology. The 12-month internships provide training and experience with mentally and emotionally handicapped children, adolescents, and young adults. A combined stipend and housing allowance ranging from \$5,100 to \$7,500 (\$3,600 is tax exempt) is available to qualified applicants who are U.S. citizens. For information write to Henry Platt, Director, The Devereux Foun-

dation, Institute of Clinical Training, Devon, Pennsylvania 19333.

Eastern Virginia Medical School Department of Psychiatry and Behavioral Sciences and Psychiatric Associates of Tidewater, Norfolk, Virginia: Now accepting applications for pre- and postdoctoral internship in clinical psychology beginning September 1975. Program offers advanced, closely supervised experiences in a variety of clinical activities in both a comprehensive community mental health center and a private psychiatric facility offering both inpatient and outpatient services. Stipend: \$5,000-\$7,000. For further information write to William L. Scarpetti, Director, Division of Psychology Education and Services, Department of Psychiatry and Behavioral Sciences, Eastern Virginia Medical School, P.O. Box 1980, Norfolk, Virginia 23501.

Johns Hopkins University School of Medicine, Division of Psychology, John F. Kennedy Institute for Habilitation of the Mentally and Physically Handicapped Child: One- and two-year postdoctoral fellowships available, providing experience in the use of behavior modification techniques for identification and treatment of the exceptional child in a major interdisciplinary setting. Applicants must have a PhD in psychology or a related discipline prior to appointment. Stipends: \$6,000-\$7,000 for first year with \$600 dependent allowance. For further information write to J. Dardano, Division of Psychology, John F. Kennedy Institute, 707 N. Broadway, Baltimore, Maryland 21205.

Langley Porter Neuropsychiatric Institute, University of California in San Francisco: Announces internship openings for clinical psychology PhD

candidates. These internships are available to students who have completed at least two years in graduate clinical psychology programs in APA-approved universities. Uncertain and limited funding makes us particularly interested in qualified applicants who can bring their own funds. For further information write to Director of Training in Clinical Psychology, Langley Porter Neuropsychiatric Institute, University of California, San Francisco, California 94143.

University of Maryland School of Medicine: Now accepting applications for pre- and postdoctoral internships in pediatric and clinical child psychology presenting comprehensive field training in clinical child, pediatric psychology, and developmental disabilities. The pediatric program is administered by the Pediatric Psychology Staff of the Department of Pediatrics at the University of Maryland. Stipends: \$5,000. For further information write to Thomas Kenny or Rudolph Bauer, Department of Pediatrics, University of Maryland Hospital, Medical School, Lombard and Greene Streets, Baltimore, Maryland 21201.

Meyer-Manhattan Psychiatric Center: Now accepting applications for internships in psychology for September 1975. Primary objective is to provide as broad a range as possible in psychological diagnosis, work on inpatient wards, day hospital, outpatient, and other mental health facilities. A specialization in community or behavior modification is also available. For further information write to Saul A. Grossman, Chief Psychologist, Meyer-Manhattan Psychiatric Center, Ward's Island, New York 10035.

Reiss-Davis Child Study Center: Now accepting applications for the two-year postdoctoral training pro-

gram in intensive psychoanalytically oriented clinical child psychology. Program includes supervised experience in the diagnostic and psychotherapeutic processes, related seminars, and opportunity for experience in brief psychotherapy. For further information write to Esther Lampl, Director of Psychological Services, Reiss-Davis Child Study Center, 9760 West Pico Boulevard, Los Angeles, California 90035.

University of Wisconsin Medical School: Announces a postdoctoral fellowship in clinical psychology offering advanced training in a variety of psychotherapeutic modalities with adults and children, community and hospital consultation, crisis intervention, and inpatient treatment. Fellowship is for 1 or 2 years. Basic stipend is \$6,000, with possible supplementation to a maximum of

\$8,000; the first \$3,600 is tax exempt. There is an allowance of \$600 per dependent. Applicants must have a PhD in clinical psychology and a clinical internship. Preferred starting date is July 1, 1975. For further information write to David G. Rice, Department of Psychiatry, University of Wisconsin Medical School, 1300 University Avenue, Madison, Wisconsin 53706.

Distinguished Professional Contribution Award

The Distinguished Professional Contribution Award is presented annually to a member of the Association who has advanced psychology as a profession by distinguished contributions to knowledge or practice, subject to the following limitations: (a) members of the award committee, former recipients of the award, the President and the President-elect of APA are ineligible; (b) the committee shall seek diversity in selecting recipients, avoiding as far as possible the consecutive selection of more than one person representing a specialized topic, a specific material, a given method, a particular application, or a specific specialized service. The winner receives \$1,000. The award was first given to Carl R. Rogers in 1972. In 1973 the winner was David Wechsler, and in 1974, Noble H. Kelley. Those wishing to submit a nomination are asked to write for nomination forms to: Professional Award, Department of Professional Affairs, APA, 1200 Seventeenth Street, N.W., Washington, D.C. 20036. *Deadline for nominations is May 15, 1975.*

The child is father to the man

Poetic words, written before there was a suitable way to validate their empirical truth. But as it turns out, they express quite accurately what developmental psychology is all about.

The study of human development—it's exciting, stimulating, and comprehensive with McGraw-Hill texts.

CHILD PSYCHOLOGY: A CONTEMPORARY VIEWPOINT E. Mavis Hetherington and Ross D. Parke

This challenging text depicts child psychology as a scientific discipline by exposing students to contemporary theory, empirical data, controversies, and research methods. The authors identify the processes underlying human development as well as the developmental changes themselves. They give considerable attention to early experience and discuss the significant developmental changes that occur throughout childhood and adolescence in cognition, intelligence, language, learning, genetics, and socialization.

CHILD PSYCHOLOGY: A Contemporary Viewpoint

Topically organized . . . research based . . . an outstanding text.

1975, 608 pages, \$11.95.

Instructor's manual available.

DEVELOPMENTAL PSYCHOLOGY, Fourth Edition Elizabeth B. Hurlock

Now tailored to one-semester courses in developmental psychology, the fourth edition of this classic life-span text has been trimmed to half the size of previous editions. Easier to use and more efficient, this edition features stimulating new illustrations, highlighting boxes, and chapter summaries to spark interest and aid retention. Current topics now include sex roles, the problems of aging, and changing attitudes toward death and dying.

DEVELOPMENTAL PSYCHOLOGY, Fourth Edition

Comprehensive, authoritative, and highly successful.

1975, 416 pages, \$11.95. Instructor's manual available.

Prices subject to change.

Now! A truly new teaching aid —

BASIC RESEARCH LITERATURE IN SUMMARY FORM!

Empirical Studies in the PSYCHOLOGY OF LEARNING

Abstracted by B. R. BUGELSKI

*Distinguished Professor of Psychology,
SUNY at Buffalo*

FOR YOU: A highly flexible work that can be used alone or in combination with any traditional text. Includes most of the experimental papers you want your students to read.

FOR THE STUDENT: His own 6" x 9" library of 100 years of research — for \$3.95!

356 Pages

62 Illustrations

\$3.95 Paperback

Includes studies ranging from EBBINGHAUS to THORNDIKE, PAVLOV, TOLMAN, GUTHRIE, SPENCE, SKINNER, et al., through the most distinguished contributors of the 1970's.

THE AUTHORS SPEAK FOR THEMSELVES. NO EDITORIAL COMMENT INTRUDES. THE ABSTRACTED PAPERS RANGE OVER CLASSICAL ISSUES IN ASSOCIATION, PAVLOVIAN CONDITIONING, INSTRUMENTAL CONDITIONING, VERBAL LEARNING, AND BEHAVIOR MODIFICATION.

"By carefully summarizing in the manner of the original author, Bugelski provides the student with an extraordinarily large number of studies presented in historical perspective and almost in original form. Thus the material can be organized historically, conceptually, or in some combination. Invaluable as assigned reading."

—DAVID EHRENFREUND, *Southern Illinois Univ. at Carbondale*

Psychology Lives!

... in Saunders texts...

Millon & Millon: Abnormal Behavior and Personality

A Biosocial Learning Approach

The origins, development and functions of abnormal behavior are examined in the light of social learning theory in this introductory text. The authors' approach differs from other social-learning models in their recognition of individual biological tendencies as determinants of behavior, and in their coverage of abnormal personalities in everyday life—thus establishing continuity between milder pathologies and more severe disorders. By **Theodore Millon** and **Renee Millon**, Univ. of Illinois. 535 pp. *Illustd.* \$11.95. Feb. 1974.

Order #6390-7.

An Instructor's Manual is available.

A **Study Guide**, by **Lella Foster** and **Theodore Millon**, highlights important theories and briefly summarizes each chapter of the Millon & Millon text. Review questions are included. 112 pp. \$3.50. Feb. 1974.

Order #3819-8.

Millon: Theories of Psychopathology and Personality

Essays and Critiques—2nd Edition

Fifty-nine of the world's most respected clinicians and theorists make the second edition of this popular anthology a truly authoritative sourcebook. Papers are grouped according to the type of data they emphasize: biophysical, intrapsychic, phenomenological, behavioral, sociocultural, and integrative. Edited by **Theodore Millon**. 502 pp. *Soft cover.* \$5.95. April 1973.

Order #6382-8.

Johnson: Aggression—In Man and Animals

Aggressive behavior in more than 150 species is described here, but the emphasis is on man—his guns, drugs, racial tensions, televised violence and war. It's a hard-hitting text applicable to almost any undergraduate psychology course. By **Roger N. Johnson**, Ramapo College, N. J. 269 pp. *Illustd.* *Soft cover.* \$4.50. April 1972.

Order #5160-7.

Voeks: On Becoming an Educated Person—3rd Edition

One of the best guides available on teaching students how to learn—through proper study habits, attention, and attitudes. By **Virginia Voeks**, San Diego State College. 278 pp. *Illustd.* *Soft cover.* \$2.95. June 1970.

Order #9066-1.

DiCaprio: Personality Theories

Guides to Living

This life-oriented approach to the study of personality analyzes the views of major theorists as applied to specific aspects of personality—development, learning, needs and motivation, conflict, and the search for "the good life." The material both fosters an understanding of individual behavior and relates directly to everyday living, making it uniquely adaptable for use in adjustment courses as well as personality courses. By **Nicholas S. DiCaprio**, John Carroll Univ., Cleveland. 502 pp. *Illustd.* \$10.95. July 1974.

Order #3055-3.

An Instructor's Manual is available.

Shope: Interpersonal Sexuality

General and developmental aspects of human sexuality are fully described, with an emphasis on interpersonal relationships and psychosocial functions rather than genital sex. Special consideration is given to premarital sex, sexuality and morality, and children's sexual development. Designed for courses in human sexuality, it's an excellent auxiliary text for behavioral science as well. By **David F. Shope**, Pennsylvania State Univ. About 385 pp. About \$7.50. Ready January.

Order #8253-7.

Sattler: Assessment of Children's Intelligence

The complete spectrum of intelligence testing in children is covered here in a single volume. It shows how to best administer tests; how to use them to evaluate mental disorders, mental retardation or learning disabilities; and how to most effectively test minority group children. Major coverage is of the Stanford-Binet and Wechsler (WISC/WPPSI) batteries, though others are included. An upcoming reprint of the text will also include coverage of the WISC-R and the 1972 Binet norms. By **Jerome M. Sattler**, San Diego State Univ. About 575 pp. About \$14.95.

Order #7944-7.

Kaufmann: Introduction to the Study of Human Behavior

Here's valuable supplementary reading for introductory courses in personality, social psychology, and educational psychology. Dr. Kaufmann examines the rationale for, and the methods used in the scientific study of human behavior. By **Harry Kaufmann**, Hunter College, CUNY. 162 pp. *Illustd.* *Soft cover.* \$2.50. April 1968.

Order #5300-8.

LONDON'S BEGINNING PSYCHOLOGY

Perry London's **BEGINNING PSYCHOLOGY** talks to today's students and what it says is...

"WELCOME TO PSYCHOLOGY

You're going to like this treatment"

- *a balance between humanism and empiricism*
- *excellent writing - a contemporary tone*
- *up-to-date research data*
- *key terms underlined to promote vocabulary building*
- *end of chapter summaries highlight major points*
- *extensive glossary*

BEGINNING PSYCHOLOGY

by Perry London, *University of Southern California*

This smooth straightforward presentation was designed to make Psychology an exhilarating, personal, experience for the beginning student.

Although scholarly and comprehensive, London's book speaks clearly to unsophisticated undergraduates by describing complicated facts and theories in simple terms. At the same time, more knowledgeable students will easily grasp the complexities and nuances inherent in the text.

The author places psychology in evolutionary, historical, and contemporary perspective. His writing style is personal and his approach eclectic and interdisciplinary.

Traditional subject matter comes to life in this fresh, often witty, literary work.

Student Workbook and Study Guide

by Robert Pellegrini, *California State University—San Jose*

Each chapter in the *Student Workbook and Study Guide* includes:

- An overview of chapter material from the text
- A review of mastery objectives
- A Study Unit with fill-in questions and self tests
- Exercises at the end of the chapter illustrating how principles stated in each chapter apply to student's personal experiences

TEST BANK: Multiple choice—true/false questions for each chapter.

This colorfully illustrated text includes over 60 line illustrations—22 portraits of prominent men—127 reproductions of fine art accompanied by captions designed to amplify specific concepts discussed in the chapter.

Examination copies for adoption consideration available on request; please indicate course title and text presently used.

THE DORSEY PRESS

Homewood, Illinois 60430

Thesaurus of Psychological Index Terms

Contains over 4,000 terms representing an authoritative, unambiguous, and hierarchically structured vocabulary used by psychology and related disciplines. This vocabulary will facilitate precise content representation of concepts described in psychological literature and allow for more flexibility in automated search and retrieval operations. These two factors promote more effective communication of psychological concepts in original works and research, ultimately aiding the content of publications to be focused in accordance with the interest patterns of psychologists.

This **Thesaurus**, developed by the Psychological Abstracts Information Services, is divided into three sections:

The **relationship section** shows the relationships among concepts that are associated with each other. Term relationships noted are: synonymous, broader, narrower, or related.

The **alphabetical section** presents each preferred term in alphabetical order, enabling rapid identification of terms used for indexing.

The **hierarchical section** contains 17 broad content areas in which terms are presented in descending order according to breadth of concept represented. The 17 categories correspond to major classifications used in *Psychological Abstracts*.

The relationship, alphabetical, and hierarchical sections will assist the user in selecting appropriate terms for different uses.

Administrators

- determine areas of research for an organization
- assure representative expertise in personnel selection

Researchers and Authors

- find synonyms for a term representing a concept
- select terms that represent a concept
- define subject matter topics for a paper or book

Educators

- structure a curriculum
- use as a tutorial aid

Consultants

- search the literature
- aid in retrieval of information

Librarians

- provide access to psychological literature
- aid in cataloging psychology material
- aid in ordering new psychological literature

Students

- locate concepts relevant to psychology
- focus areas of study

The **Thesaurus** contains 362 pages with a hard-cover and costs \$12. Please note that all orders amounting to \$15 or less must be accompanied by full payment except for those orders submitted on institutional purchase order forms.

psychology

from harper & row

Announcing:**INTRODUCTION TO PHYSIOLOGICAL PSYCHOLOGY****RICHARD F. THOMPSON**

Expressly written for the first undergraduate course in physiological psychology, this text is broader in scope and less rigorous than the author's *FOUNDATIONS OF PHYSIOLOGICAL PSYCHOLOGY*. It is a broadly based introduction to the physiological bases of behavior and experience which highlights the current and exciting developments in the field. No previous background in psychology or biology is required since all concepts are discussed and explained when introduced in the text. Biological systems and processes that underlie behavior and experience are presented, with emphasis on brain mechanisms, in the broader context of the fundamental concepts and issues in psychology. Topics include many of special interest to students such as the actions of psychedelic drugs on the brain and awareness and sexual differentiation in humans. Over 200 drawings and photographs illustrate the text. Tentative: 576 pages; \$13.95. February 1975.

The Study Guide by Richard A. Roemer contains over 1,000 questions. \$4.95 (tentative).

THE PSYCHOBIOLOGY OF SENSORY CODING**WILLIAM R. UTTAL**

"This clearly presented text offers a most perceptive and up-to-date coverage of issues and data in the field of sensory psychology. . . . This book is unique in that we are given a thoughtful and insightful analysis that compares coding processes in the various sensory systems."—*Choice*/678 pages; \$16.95. 1973.

FOUNDATIONS OF EXPERIMENTAL RESEARCH**Second Edition****ROBERT PLUTCHIK**

This text views experimentation as a decision-making process that begins with a problem and ends with the publication of a report. The definition of key concepts, the sampling of subjects and conditions, measurement, scaling, instrumentation, design, and statistics are identified as the main decision areas concerned. 331 pages; \$6.95/paper. January 1974.

A PRIMER OF PHYSIOLOGICAL PSYCHOLOGY**ROBERT L. ISAACSON, ROBERT J. DOUGLAS,
JOEL F. LUBAR, and LEONARD W. SCHMALTZ**

295 pages; \$10.95. 1971. Instructor's Manual. Study Guide: \$3.95.

A FIRST READER IN PHYSIOLOGICAL PSYCHOLOGY**JOEL F. LUBAR, Editor**

344 pages; \$6.95/paper. 1972.

Harper & Row / 10 East 53d Street, New York 10022

*The beginning is
the most important part
of the work.**

*He has half the deed done
who has made
a beginning.**

*Be favorable
to bold beginnings.**

Twentieth century research has proved these sages right. The kind of beginning people get — in life, in work, or in studies — has a lot to do with their future successes and failures. Give your students a solid foundation — introduce them to psychology with a distinguished text.

Introduction to Psychology, FIFTH EDITION

Clifford T. Morgan and Richard A. King

An objective approach to the foundations of human thought and behavior, this well-known text presents a clear and logical overview of modern psychology. It's flexible—comprehensive enough for two-semester courses, rigorous enough for science-oriented courses, and a good choice for life-oriented courses, as well. Behavior is the focus of the study, but the book is not narrowly behavioristic. This thorough revision is shorter than the previous

edition, and approximately 75% of the revised material is new. Major changes include more emphasis on learning and the cognitive processes, new chapters on the development of behavior and language, a heavily revamped illustration program, and the integration of physiological material into the text. The study guide and instructor's manual are organized so that they are equally suited for use in "unit mastery" courses or traditional lecture courses. 1974, 736 pages, \$12.50

Another significant beginning . . . the challenge to read, consider, and interpret.

Readings in Psychology: THE SEARCH FOR ALTERNATIVES

THIRD EDITION James A. Dyal, William C. Corning, and Dale M. Willows

Thought-provoking selections are combined with a format which promotes *active* learning in this fresh approach to readings in psychology. "On the spot" questions and blank spaces for immediate response

are sprinkled throughout the text, encouraging students to ask questions and make notes as they read. By selecting current topics and juxtaposing contradictory published opinions about them, the authors have created a provocative collection that encourages readers to do their own thinking. 1975, 420 pages, paper, \$6.95

Prices subject to change.

**Quotes (left to right): Plato, The Republic; Horace, Epistles; Virgil, Georgics.*

College & University Division / MCGRAW-HILL BOOK COMPANY
1221 Avenue of the Americas, New York, N. Y. 10020

"...to listen with an honest and open mind, to convey to a patient that one is available for his journey of self-discovery but with the implication, from the beginning, that this can be successful only when both undertake the journey together."*

This is how Dr. Hilde Bruch describes a therapist's work. With great wisdom and sensitivity, she draws on her 30 years of experience to teach others the art of psychotherapy.

Dr. Otto Allen Will, Jr.,
Medical Director, Austen Riggs

Center, says: "Hilde Bruch's book is a masterpiece of succinct and clear statements about the major and fundamental issues of psychotherapy. It will be a first-rate text for anyone interested in furthering his skills as a psychotherapist." **\$8.95**

HOW BEHAVIOR MEANS

Albert E. Schellen One of the pioneers of kinesic studies explores the total network of human communications — not just words, intonations and posture, but also the settings of an exchange and the "roles" and cultural backgrounds of the participants. Paperbound, \$2.50

PERSONALITY AND POLITICS

Gordon J. DiRenzo. This collection of essays examines the interrelations of class, status, personality types and political processes and gives rise to a theory that rejects any sociological, psychological or political reductionism. A Doubleday Anchor Original. Paperbound, \$3.50

FREUD

A Collection of Critical Essays

Edited by Richard Wollheim. Jean-Paul Sartre, Ludwig Wittgenstein, Stuart Hampshire and 18 others join in this re-appraisal of Freud's ideas from a philosophical perspective. A Doubleday Anchor Original/Modern Studies in Philosophy Series. Paperbound, \$4.95

THE PSYCHOANALYSIS OF WAR

Franco Fornari. How have theories from Freud to Money-Kyrle sought to explain the origins of war? Are these theories still valid in the nuclear age? Franco Fornari offers provocative answers in this far-reaching study. A Doubleday Anchor Original. Paperbound, \$2.95

ON NOAM CHOMSKY

Critical Essays

Edited by Gilbert Harman. Prominent philosophers, linguists, psychologists and anthropologists probe the broad implications of Chomsky's innovative theories of linguistics. A Doubleday Anchor Original/Modern Studies in Philosophy Series. Paperbound, \$4.95

Doubleday & Company, Inc.

A very special book about a very special world...

The diversified environments in which children actually grow and develop are reflected in this challenging introductory text. The book is chronologically structured, offering a contemporary perspective on the development typical of most

children at each stage from conception through adolescence. Covered in depth are current and historical approaches to research and theory; normal and atypical prenatal development; the sequence and timing of normal physical, mental, social, emotional, and personality development; and genetic and environmental factors that influence human development. Text discussions are reinforced by descriptions of Vicky, a representative composite child who "grows up" throughout the text, illustrating theories, principles, and empirical data in a vivid and colorful way. 1975, \$10.95, 512 pages. Instructor's Manual/Test File available.

Price subject to change.

Historical Introduction to Modern Psychology

THIRD EDITION

GARDNER MURPHY, *George Washington University*
JOSEPH K. KOVACH, *The Menninger Foundation*

A major revision of a classic textbook that provides a rich, coherent, and up-to-date presentation of the development of modern psychology—the evolution of research and theory, systems of psychology, methods of thought and work, and the social and intellectual contexts of important figures and schools. **526 pages**

The Adolescent Years

SECOND EDITION

WILLIAM W. WATTENBERG, *Wayne State University*

A popular textbook for adolescent psychology that offers a comprehensive examination of the problems and experiences of the developing adolescent, and that applies generalized psychological theory to specific behavior, thoughts, and feelings. **456 pages**

Readings in Child Behavior and Development

THIRD EDITION

CELIA STENDLER LAVATELLI, *University of Illinois*
FAITH STENDLER, *Massachusetts Mental Health Center*

A highly successful reader for courses in child development and child psychology that offers 46 important theoretical statements and research articles (42 new to this edition) on such major concerns as infancy, cognitive development, and the disadvantaged. With lengthy introductory essays to each of six parts that discuss the current thinking in the field, place the selections in context, and provide detailed bibliographies. **526 pages**

Personality

DYNAMICS, DEVELOPMENT, AND ASSESSMENT

IRVING L. JANIS, *Yale University*
GEORGE F. MAHL, *Yale University*
JEROME KAGAN, *Harvard University*
ROBERT R. HOLT, *New York University*
IRVING L. JANIS, *Volume Editor*

A distinguished full-scale introduction to the study of personality by four leading psychologists, each a specialist in the area with which he deals. "Stress and Frustration," by Irving L. Janis, examines the personality changes provoked by stressful and frustrating events. "Conflict and Defense," by George F. Mahl, emphasizes the empirical observations and related clinical concepts of psychoanalysis pertaining to inner conflict and defense, and also draws on learning theory and other psychological perspectives. "Personality Development," by Jerome Kagan, highlights the major phenomena of personality development within a descriptive and eclectic framework to provide a clear understanding of the motivations and emotions of a child's progress toward maturity. And "Assessing Personality," by Robert R. Holt, offers a solid introduction to personality assessment that considers informal and formal assessment, and the contributions of both the clinical and objective traditions. **559 pages**

Also available in four paperback volumes:

STRESS AND FRUSTRATION 215 pages
PSYCHOLOGICAL CONFLICT AND DEFENSE 222 pages
PERSONALITY DEVELOPMENT 181 pages
ASSESSING PERSONALITY 245 pages

Keller's Personalized System of Instruction: An Appraisal

Bruce A. Ryan, author; *Foreword* by Fred S. Keller. Offers the reader an objective assessment of the relevance of behavior theory, the role of unit tests, the appropriateness of the student proctor, and the success of self-evaluation in this increasingly popular approach to college-level education. In addition to an analytical review of the current literature, future directions for PSI are proposed and an invaluable "how-to" bibliography is included. 1974. 32 pp. \$2.

CHARLES C THOMAS • PUBLISHER

SOCIETAL STRUCTURES OF THE MIND by Uriel G. Foa, *Temple Univ., Philadelphia*, and Edna B. Foa, *Temple Medical School, Philadelphia*. This volume is addressed to professionals and advanced students in psychology, psychiatry, sociology, anthropology, education and social work whose main concern lies in understanding interpersonal relations in the context of societal structures. The reader is provided with a comprehensive description of the mechanisms by which interpersonal behavior is regulated, along with their development and function in social encounters. Written in a simple, concise style, this book integrates the results of several decades of research by scores of investigators. '74, 468 pp. (6 3/4 x 9 3/4), 13 il., 67 tables, \$21.50

THE PSYCHOLOGY OF OBESITY: Dynamics and Treatment edited by Norman Kiell, *Brooklyn College, Brooklyn, New York*. (47 Contributors) This volume delineates the best efforts of professionals in many disciplines, psychoanalysts, psychiatrists, psychologists, internists, sociologists, demographers, anthropologists and nutritionists, to solve the puzzle of obesity. The articles have been written by some of the foremost authorities in the field and cover the panorama of problems as well as the complexities of people. The articles range from discussions of dynamics and etiology to body image and self-concept; psychosocial factors; the varieties of techniques and therapies, including individual and group techniques; hypnosis with children, adolescents and adults; dieting and psychometrics. '73, 480 pp. (6 3/8 x 9 5/8), 41 tables, \$13.95

CRISIS INTERVENTION AND COUNSELING BY TELEPHONE edited by David Lester, *Stockton State College, Pomona, New Jersey*, and Gene W. Brockopp, *Suicide Prevention and Crisis Service, Buffalo, New York*. (23 Contributors) The first part of this book reviews some of the ways telephone counseling and crisis intervention have been utilized by different agencies such as the suicide prevention center, the teenage hotline and the individual psychotherapist. A second section examines the ways in which telephone counseling differs from other modes of counseling including one-to-one individual counseling, group psychotherapy and others. The unique features of counseling clients by telephone are also discussed. The third and fourth parts examine the problems, propose ways in which these problems can be handled and discuss the selection and training of those who perform the counseling over the telephone. '73, 336 pp., 6 il., 15 tables, \$11.95

MICROCOUNSELING: Innovations in Interviewing Training (3rd Ptg.) by Allen E. Ivey, *Univ. of Massachusetts, Amherst*. Contribution by John R. Moreland. Foreword by Robert R. Carkhuff. The author provides a new format through which the interviewing process may be examined with increased meaning and rigor. The text describes a systematic approach to teaching interviewing skills, which has been shown to be useful in training not only clinical and counseling psychologists but also social workers, paraprofessionals and numerous other members of the helping professions. Microcounseling provides not only a vehicle for teaching skills but also a structure upon which one can build his own concept of interviewing, counseling and therapy. '74, 228 pp., 1 il., 1 table, \$9.75

THERAPEUTIC NEEDS OF THE FAMILY: Problems, Descriptions and Therapeutic Approaches edited by Richard E. Hardy, *Virginia Commonwealth Univ., Richmond*, and John G. Cull, *Virginia Commonwealth Univ., Fishersville*. (15 Contributors) The editors have shown considerable talent in bringing together a combination of practical and theoretical material consisting of a collection of writings by professional leaders in the field of family work and marital adjustment. This book bridges the gap in the professional literature between the more theoretically oriented material of academia and the more practical problem descriptions which concern the practitioner on the firing line in problem situations. Some of the topical areas included are group work with distressed families, families in crisis, family crisis intervention, the child of divorce, family therapy in the treatment of adolescents with divorced parents and case study descriptions. '74, 256 pp., \$11.75

ADJUSTMENT TO WORK edited by John G. Cull, *Virginia Commonwealth Univ., Fishersville*, and Richard E. Hardy, *Virginia Commonwealth Univ., Richmond*. (17 Contributors) Beginning with the meaning of work, this book covers the relationship between work adjustment and leisure adjustment, vocational evaluation and work adjustment in rehabilitation, special problems of the mentally ill in adjustment to work, special problems of the disadvantaged and mentally retarded, the contribution of psychological evaluation to work adjustment, the contribution of group work, and theory and research in work adjustment. In essence this book uses a carefully solicited collection of writings which have not been previously published. '73, 360 pp., \$16.75

Announcing a major publishing event:

Over 12,000 references are cited in this volume, devoted to the major publications of 538 contributors to psychology who lived between 1600 and 1967. (A second volume, in preparation, will contain selected secondary references to the work of the same contributors.)

The individuals represented were chosen by an international panel of leading psychologists, on the basis of a precisely formulated system of rating. Both the method of ascertaining eminence and the criteria for the selection of references are described in the editor's *Introduction*, which is followed by a concise guide to the use of the volume. This truly impressive reference source fills a need long felt in the field of psychology, bringing together the totality of its significant literature.

PSYCHOLOGICAL STRESS

Psychoanalytic and Behavioral Studies of Surgical Patients

by IRVING L. JANIS

Reprinted by Academic Press, Inc.

Psychological Stress is a brilliant empirical and theoretical investigation of human emotional reactions and thought processes in times of external threat and danger. Professor Janis was awarded the Hofheimer Prize of the American Psychiatric Association for this book as "an outstanding research contribution in the field of mental hygiene." Widely acclaimed by psychologists and psychiatrists alike, this illuminating study is used as a textbook in many medical and nursing schools. It includes an extensive bibliography, an Author Index, and a Subject Index. Part One, which contains a detailed case study, is devoted to elucidating the impact of external events (in this case, surgery) on a patient undergoing psychoanalytic treatment. In Part Two, the major psychoanalytic hypotheses that emerge from the case study are assessed in the light of additional evidence. This evidence takes two main forms: 1) a series of intensive interviews conducted in the surgical wards of a hospital before and after each patient's operation; 2) a questionnaire survey of the surgical experiences of several hundred young men. The author not only discusses the theoretical significance of his research, but also outlines effective methods for alleviating the emotional strain which accompanies physical suffering.

PSYCHOLOGY OF LEARNING AND MOTIVATION, Volume 8

Advances in Research and Theory

edited by GORDON H. BOWER

CONTENTS: Semantic Memory and Psychological Semantics. Working Memory. The Role of Adaptation-Level in Stimulus Generalization. Recent Developments in Choice. Reinforcing Properties of Escape from Frustration Aroused in Various Learning Situations. Conceptual and Neurobiological Issues in Studies of Treatments Affecting Memory Storage. The Logic of Memory Representations.

1974, 320 pp., \$24.50/£11.75

ADDICTION

edited by PETER G. BOURNE

Recent years have seen a spectacular increase in heroin addiction in the United States. One result of the epidemic has been the generation of enormous amounts of new information on heroin addiction—information that is only gradually being assimilated into a new understanding of the problem. In this volume, leading authorities in the field provide new insights into the heroin epidemic of the late sixties. Each contributor was asked to discuss those issues that were uppermost in his mind or which he felt were of special topical concern. The result is a series of authoritative statements on topics ranging from the politics and history of addiction to current treatment techniques. It includes a chapter by Dr. Robert Dupont, Director of the National Institute for Drug Abuse, and Director of the President's Special Action Office for Drug Abuse Prevention.

1974, 256 pp., \$17.50/£8.40

ARTIFICIAL INTELLIGENCE

by EARL HUNT

A Volume in the ACADEMIC PRESS SERIES IN COGNITION AND PERCEPTION Series

This book provides a detailed, unified discussion of the fundamental approaches to the problems of artificial intelligence. The author emphasizes principles, not details. He believes that artificial intelligence is based on certain well-understood concepts in applied mathematics, statistics, mathematical logic, and psychology—and that an attack on the unsolved conceptual problems in these areas is of more value than studies of the latest robots or machine chess players. Topics covered in detail include pattern recognition, deductive problem solving, theorem proving, perception of the physical world (vision and speech) by machine, and comprehension of natural language. The book stresses throughout ways in which basic concepts may be applied to the specific algorithms and programming concepts for these applications.

1974, about 458 pp., in preparation

PLASTICITY AND RECOVERY OF FUNCTION IN THE CENTRAL NERVOUS SYSTEM

edited by DONALD G. STEIN, JEFFREY J. ROSEN and NELSON BUTTERS

The chapters comprising this volume comprehensively discuss the nature and scope of recovery of function after CNS damage. They cover, not only what is now known on this relatively new area of CNS plasticity, but also almost all the methodological and theoretical approaches to its study. Topics discussed include: historical concepts of localization of function and its relationship to CNS plasticity, according to current concepts, original research on developmental plasticity in the CNS, emphasizing morphological and anatomical changes underlying plasticity (or its lack) in the developing nervous system, behavioral recovery in developing organisms—including several theories to account for retention of function in neonatal specimens tested long after the damage has been inflicted, the process of recovery of function in adult organisms; and clinical examples of recovery (or lack of it) in human beings.

HUMAN INFORMATION PROCESSING: TUTORIALS IN PERFORMANCE AND COGNITION

Edited by Barry H. Kantowitz

This advanced text presents highly technical material in a graduated fashion with minimal assumption about the reader's prior knowledge. It emphasizes methodology and models rather than merely surveying the literature in the field. Thus it should help protect the researcher who is new to an area from some of the common errors made in the past. Each chapter aims at balanced coverage of a topic, and is intended as a general reference for sophisticated researchers and teachers. The book emphasizes performance and cognition as related aspects of human information processing.

HUMAN COMMUNICATION: THEORETICAL EXPLORATIONS

Edited by Albert Silverstein

This volume treats the entire spectrum of problems related to human communication. It does so at the level of general theory and processes, from the varying viewpoints of creative scholars drawn from the various disciplines that address the issues involved in human communication. The book is organized so that there is progression toward increasingly more complex levels of analysis, beginning with issues related to the nature of physical signals used in speech, and proceeding to issues involving ongoing two-person discourse, and issues related to the impact of various media of modern communication. Each chapter both outlines the range of problems within its domain and presents the theoretical approach of each of the distinguished contributors.
